artificial shelter is provided. Losses sometimes take place on mountain farms. The sheep are buried many feet deep in the snow; and though the shepherd, with such assistants as he can employ, armed with poles and spades, aided by the sagacity of his dog, and his skill at digging, may effect the greater number perish. While the sheep remain in artificial shelters of any kind they must of course be fed; and the only convenient food in such cases is hay, straw, or dried spray (the latter seldom resorted to in this country, which should be put into baskets, or racks. (Fig. 804.) The Ryeland breed of sheep in Herefordshire, and some other parts of the highlands in the north, are put under cover nightly throughout the year: a practice which has probably originated in security, and been continued as matter of convenience and habit.

Sect. V. Folding of Sheep.

7208. Cotting or folding is a practice more or less extensively followed with particular breeds and in particular districts, but now generally on the decline.

7209. It was formerly thought to be indispensably necessary to the success of the farmer in different districts; but of late a different opinion has prevailed, except in particular cases, and it is considered as merely enriching one field at the expense of another. The practice may, however, be beneficial where there are downs, heaths, or commons. Folding has been chiefly confined to England, and a small part of Wales and Ireland. The object is to enrich the arable land; but as this is done at the expense of the pasture, it is truly, as Bakewell expressed it, "robbing Peter to pay Paul."

7210. The sheep recommended to the farmer are those of the more active and short-wooled varieties, such as the Norfolk, Wiltshire, and South Down breeds; the heavy long-wooled kinds being less Hardy, and some of them, as the Leicester, much too valuable for a mode of treatment that converts them into dung carriers. The following calculations by Börlin show, that though, in open lands, the practice may be in some cases tolerated on the ground of convenience or expediency, it can possess no recommendation as a profitable mode of management in other circumstances.

7211. This morning (September 22, 1750), measured a sheep-fold, set out for six hundred sheep, consisting of ewes, wethers, and growing lambs. Its mean land is twenty acres, which measures eight by five and a half rods, which is somewhat more than seven rods to one hundred, or two yards to a sheep.

7212. Last autumn made an accurate experiment, on a large scale, with different manures for wheat. On a sandy loam, summer followed. Part of an eighteen acre piece was manured with fifteen or sixteen loads of tolerably good twice; the rest folded upon with sheep dung twice; the first time at the rate of six hundred sheep to a quarter of an acre (as in first minute), the second time thimber. In winter and spring, the dung kept the land; and now, at harvest, it has produced the greatest bards of straw. The sheep-fold kept a steady pace from seed-time to harvest, and is now evidently the best corned, and the cleanest crop. The line, in winter and spring, made a poor appearance, but after some showers in summer it flourished much, and is now a foot high. A crop of three quarters of an acre.

7213. From these data the value of a sheep-fold, in this case, may be calculated. It appears from the first minute, that one hundred sheep manured seven square rods daily. But the second folding was thinner; suppose nine rods, this, on a part of the two foldings, eight rods a day each folding. The dung could not more than two, and the carriage and spreading ten shillings an acre; together fifty shillings an acre; which quantity of land the hundred sheep teathed twice in forty days. Supposing them to be folded the year round, they would, at this rate, fold nine acres annually; which, at fifty shillings an acre, is twenty-two pounds ten shillings a hundred, or four shillings and sixpence a head. In some parts of the island, the same quantity of dung would be worth five pounds an acre, which would raise the value of the teatich to nine shillings a head; which, at two-pence a head a week, is more than the whole year's keep of the sheep. It does not follow, however, that all lands would have received equal benefit. The results in consideration of the manures, perhaps, had not been calculated for. For manures, sheep-folds never before; and sheep folds, like other manures, may become less efficacious the longer it is used on a given piece of land. (Marshall's Rural Economy of Norfolk, vol. ii. p. 28.)

7214. Great advantage results from nearly impractical and wrong principles, where it could be done, the manure would be greatly diminished in value from rain and snow, to say nothing of the injury to the sheep themselves. So that the estimate of four shillings and sixpence, or nine shillings a head, is evidently in the extreme.

7215. According to Arthur Young Farmer's Calendar, the same land will maintain one quarter more stock when the animals are allowed to depasture at liberty, than when confined during the night in folds.

7216. The result of Parkinson's experience is, "that were the pasture sheep of Lincolnshire to be got into a fold once a week, and only caught by one, and put out again immediately, it would prevent their becoming fat." (Parkinson on Agriculture, vol. i. p. 167.) The only exception to this rule, in any extent by the best breeders, is on turnips, clover, tares, and other rich food, where the sheep feed at their ease, and manure the land at the same time.

7217. Folding in littered yards is described by Dickson (Complete Farmer, art. Sheep) as combining all the advantages of folding on arable land, and any of its disadvantages. By this practice the sheep are confined at night in a yard well and regularly littered with straw, stubble, or fern; by which means the fold is said to be kept warm and healthy in bad seasons, and at the same time a surprising quantity of manure accumulated. A great improvement on this method, it is said, would be, giving the sheep all their food (except their pasture) in such yard, viz. hay and turnips; for which purpose they may be brought up not only at night, but also at noon, to be baited; but if their pasture be at a distance, they should then, instead of baiting at noon, come to the yard earlier in the evening, and go out later in the morning. This is a practice, he says, that cannot be too much recommended; for so warm a bedding is a great matter to young lambs, and will tend much to forward their growth: the sheep will also be kept in good health; and if a point of consequence to all farms, the quantity of dung raised will be very great. If this method is pursued through the months of December, January, February, March, and April, with plenty of litter, one hundred sheep will make a dunghill of at least sixty loads of excellent stuff, which will annually manure two acres of land; whereas one hundred sheep folded (supposing the grass dry enough) will not, in that time, equally manure an acre.
PRACTICE

7218. Our opinion of this sort of folding, so warmly recommended by Sir J. Sinclair and A. Young, in the
husbandry of Scotland, concurs with that of a very superior judge, who says, "that such a method may
be considered as an experiment in certain cases; but it would be rash to deny, but generally it is
unadvisable, either on account of the sheep, or any alleged advantage from the manure they make. As to the sheep, this driving
and confinement, especially in summer, would be just as hurtful as folding them in the common way, and
it is to be feared that it would be attended with very much the same evil consequences, namely, not to be easily separated; besides, now that it is the great object of every skilful breeder to accelerate
the maturity of his sheep, as well as other live stock; among other means, by leaving them to feed at
their ease, and if circumstances permit, in such manner as to prevent the distress of the young before,
as small insects as the admirable in the weather, and without regard to manure, there can be no difficulty in converting into
tiny quantity of straw, stubble, and fern, by cattle fed in fold-yards, on green herbage in summer, and
turnips, or other succulent food, in winter; while the soil, especially if it be of a light porous quality,
is greatly benefited both by the dung brought from them and by breaking the ground, and putting the
sorts of food on the ground. It is true, that the dung of sheep has been generally supposed to be more
valuable than that of cattle, but accurate experiments have not been made to determine the difference
in this respect, among these and other polygnotic animals. The greater improvement of pastures by
sheep, is probably own, as much to their mode of feeding, as to the richer quality of their dung." (Sup. E. Brit. art. Agr.)

Sect. VI.

Of Fattening Sheep and Lambs.

7219. The subject of fattening sheep may be considered in regard to the age at which
fattening is commenced, the kind of food, and the manner of supplying it.

7220. The age at which sheep are fattened depends upon the breed, some breeds, such as the Leicester,
maturing at an earlier age than others, under the same circumstances, with regard to the abundance and
quality of the food on which they are reared; a disposition to early obesity, as well as a gradual tendency
then forms which indicates a propensity to fatten, being materially promoted by rich food, while
those which are reared in a grazing state. In a good shelter, the Leicester wethers are very generally
brought to a profitable state of fattiness before they are eighteen months old, and are seldom kept for
fattening beyond the age of two years; the Highland breeds, on the other hand, though prepared, by means of
turnips, a year at least sooner than they could be in former times, usually go to the shambles when from
the wool. The case of the first description brought brought brought brought boung
for three seasons, that is, after they have completed their fourth year, and those of the small breeds, at
from five to seven years of age, according to circumstances. (Sup. E. Brit. art. Agr.)

7221. The sort of food which best suits the sheep is good pasture, permanent or temporary; heritage
crops, as clovers, tares, &c.; turnips and other roots; and linseed cake, grains, or other edible refuse
of the oil manufactory, brewery, and distillery.

7222. The mode of feeding on rich pastures, heritage, and turnips has already been described when
treating of these crops; and it remains only to notice the modes of using grains and oil cake. These, and
also bran, oats, peas, and other grains and meals, whether given in winter or summer, should always be
accompanied with pasture or dry food of some sort, especially hay. All food of this sort should be given
in small quantities, in the middle of the day, divided in the middle, so that the sheep may feed on each side, with a sloping roof
over them, so as to cover the sheep's heads and necks while feeding, as is not only prejudicial to the
sheep but spoils the food. A rack for hay, fixed over the trough, might probably be made to answer in
this intention, while it would be very convenient for holding that material and preventing waste. The
whole of the food should be fixed on wheels and made to stand steady, and the quantity of food should
be always in readiness. In the fattening of wethers the use of barley meal, with grass or some other sort
of green food, has likewise been found highly beneficial; and, when it can be procured at a reasonable
rate, should not be neglected, as it is quick in rendering them fat, and the mutton is excellent. A pound
of oil-cake or of meal per day, with hay or turnips, for each crane or wether, is reckoned a fair allowance
in Lincolnshire.

In the report of that county several instances of oil-cake feeding are given, by which it appears that
that sort of food fattens in a shorter time than any other, is the most suitable food for fattening
sheep on a rapid promotion of the growth of the flesh. (Sup. E. Brit. art. Agr.)

7223. In fattening sheep as well as other animals, it should be made a rule never to allow them
to lose flesh, from the earliest age till they are sent to the butcher. It is found of much advantage, with a view
to keep sheep well fattened, as well as to the economy of the food, to separate a flock into divisions, corresponding with its
different ages, and the pasturage which they eat. This change from the food of store to fattening food, from that which is barely capable of supporting the condition
which they have already attained to which is adapted to their speedy improvement in fattening,
ought to be gradual and progressive. Thus very leas, or in winter, nor to rich pastures in summer; they are prepared for turnips in good grass land;
only on the after grass of rough grounds and kept on second year's leys, and afterwards a moderate allowance
of turnips if they are fatted on pastures. It is a common practice, in the instance of the Leicester,
to keep all that are not meant for breeding always in a state of fattiness, and after full feeding on turnips
through winter and spring, to finish them on the first year's clover early in summer, when the prices of
meat are usually the highest.

7224. The fattening of lambs during summer requires nothing more than keeping their
mothers and them on the richest and best pasturage, and supplying such artificial food
as the situation, season, or other circumstances may require: but the fattening of lambs during
winter and spring requires attention to three things; the breed, or if any breed be
used indifferently, the period of dropping, the lamb-house, and the feeding.

7225. With respect to the breed, as the sheep will take the ram at any season, any variety may be so
managed as to drop their lambs at any period of the year; but it is found by experience, that the Dorset-
shire sheep is easiest made to wool, and therefore this is the sort generally employed in Middlesex for
fattening lambs during winter and spring. They are not as productive as the Leicester, and therefore
ought to be house-fed, as, according to Middleton, a flock of 300 on the same manure, fed for 150
men, and butchers of London are aware that such lambs as have sharp bars on the inside of their lips
are the best, but if they are such lambs as are very deep colour and good flesh after being butchered, and that all those whose bars are naturally blunt
do as certainly produce fair meat. This knowledge has been for the last two or three years
kind being kept for rams, and sent into Dorsetshire expressly for the purpose of improving the colour
of the flesh of house-lambs; the issue of such rams can generally be warranted fair, and such meat always
sells at a higher price, hence arose the mistaken notion that Middlesex rams were necessary to procure
house-lambs.

7226. A lamb-house may be any close shed, cow-house, or other spare house, or, even on a small scale, a
roomy pigsty. But they are built on purpose by the extensive dealers in this article; and one to suckle
from one hundred and sixty to one hundred and eighty lambs at a time should be seventy feet long and
eighteen feet broad, with three coops of different sizes at each end, so constructed as to divide the lambs
according to their ages. A plan of a sheep-house, combining also a lamb-house, is given by Kraft in his Rustic Designs. It is wholly built of unbarked spars or young fir-trees. The plan (fig. 895) contains four close apartments with doors for the lambs (a, and four others with racks for the sheep (b). The elevation

(fig. 894) shows a gallery (c), which surrounds the building, and is used as a passage for viewing the sheep, handling them with the crook, and at night for the perambulations of a watch-dog. The roof being twenty feet from the floor, the interior is abundantly lighted, which is an important object in the same way (fig. 897) is accompanied by an elegant Indian watch-tower, with apartments therein for the shepherd.

7257. *The economy of the suckling-house* is as follows:—The sheep which begin to lamb about Michaelmas are kept in the close during the day, and in the house during the night, until they have produced twenty or thirty lambs. These lambs are then put into a lamb-house, which is kept constantly well littered with clean wheat straw; and health, both in lump and in powder, is provided for them to lick, in order to prevent looseness, and thereby preserve the lambs in health. As a prevention against gnawing the boards or eating each other's wool, a little wheat straw is placed, with the ears of corn, on a rack within their reach, with which they amuse themselves, and of which they eat a small quantity. In this house they are kept, with great care and attention, until fit for the butcher.

When the shoulders of the lambs are turned, every night at eight o'clock, into the lamb-house to their offspring. At six o'clock in the morning these mothers are separated from their lambs, and turned into the pastures; and at eight o'clock such ewes, if they lose their own lambs, and those ewes whose lambs were brought in and held by the head till the lambs by turns suck them clean: they are then turned into the pasture, and at twelve o'clock the mothers of the lambs are driven from the pasture into the lamb-house for an hour, in order that the latter may be the mother. At four o'clock all the ewes and their lambs of their own are again brought to the lamb-house and held for the lambs to suck; and at eight the mothers of the lambs are brought to the night.

7259. *This method of suckling* is continued all the year. The breeders select such of the lambs as become fat enough, and of proper age (about eight weeks old), for slaughter, and send them to markets during December and three or four succeeding months, at prices which vary from one guinea to four, and the rest of the year at about two guineas each. This is severe work for the ewes, and some of them die under excess of excitement, and many of them are so fat that they have plenty of food; for when brewer's gist (turnips, cole, rye, tares, clover, &c.) begins to fail, brewer's grains are given them in troughs, and second-crop hay in troughs, as well to support the ewes as to supply the lambs with plenty of milk, for if that should not be abundant, the lambs would become stunted, in which case no food could fatten them. (Middlesex Report, p. 255.)

**SECT. VII.**

**Probable Improvement to be derived from Crosses of the Merino Breed of Sheep**

7290. *The Merino, or Spanish variety of the Ovis Aries, is supposed by Rozier and other French writers to have been originally imported from Africa to Spain. It is, however, at least as probable that they are indigenous to that country, or, if originally imported, that they have become modified to what they are by the soil and climate.*

7291. *Merinos first attracted attention in this country in 1714, in consequence of the reports of travellers, and a letter by Don John Bowers to Peter Collinson, published in the Gentleman's Magazine for that year. A few were imported in 1718, and more in 1721, and placed on the king's farm at Windsor, under the care of Sir Joseph Banks, who was then constituted his Majesty's shepherd. The first sale of stock was made in 1801; and from these, a flock imported from Spain in 1801 by Lord Somerville, and some other importations by different persons subsequently, have sprung all the Merinos and Merino rams in the empire. Since that period, a number of eminent breeders and scientific agriculturists have cultivated this breed both alone and by crossing, and especially Dr. Parry and Lord Somerville, and though the utility which its introduction may add to the progress of agriculture to the country can by no means be estimated at present, that it has already done much good by directing the public attention to the subject there can be no doubt; and many are of opinion, that by it the fleeces of our short-wooled sheep may be so improved as to render them fit substitutes for imported Spanish wool.*

7292. *Dr. Parry's experiments with the Merino breed were begun nearly at the same time with the king's. His farm was elevated, exposed, and unfit for any other purpose than breeding; and he fixed on the Ryeland breed, as one of the finest woolled varieties of British sheep, for crossing with Merino rams. His only object was the improvement of the fleece.*

7293. *The effect of the fourth cross of the Merino ram, according to the opinion of sheep cultivators on the Continent, on any breed of ewes, however coarse and long in the fleece, will be to give progeny with short wool equal to the Spanish. Of the truth of this proposition, however, Dr. Parry justly expresses some doubts, derived from his own experience and that of others. But it is certain, he adds, that one cross more will, in most cases, effect the desired purpose. If we suppose, he says, the result of the mixture of the blood of the Merino ram to be always in an exact arithmetical proportion, the native blood in the ewe as 6:4; then the first cross would give 3:2 of the Merino; the second 1:3; the third 1:6; the fourth 2:5; the fifth 3:5; and so on. In other words, the first cross would leave thirty-two parts in sixty-four, or half of the English quality; the second sixteen parts, or one fourth; the third eight parts, or one eighth; the fourth four parts, or one sixteenth; the fifth two parts, or one thirty-second; the sixth one part, or one sixty-fourth, and so on. Now, if the filament of the Merino wool is coarse, or any other coarse wood, be in diameter double that of the Ryeland, it is obvious, that, according to the above statement, it would require exactly one cross more to bring the hybrid wool of the former to the same fineness as that of the latter. This, he believes, very exactly corresponds with the fact.*

3 Y 4
fherence between one eighth and one sixteenth is very considerable, and must certainly be easily perceived, both by a good microscope, and in the cloth which is manufactured from such wool. In the latter method, he adds, "it certainly has been perceived; but I have hitherto had no opportunity of trying the difference by the former method. I have before observed, that the same standard as the fourth of the Merino Ryland." (Com. to the Board of Agr. vol. v. p. 438.)

724. In the lambing season, the Ryeland breed are usually cutted, because the new born lambs are very thinly covered with wool. As January was considered the best lambing season for the produce of the cross, Dr. Parry found cutting was absolutely necessary. Even before the flock were well sheltered; and they were allowed, in addition to the pasture which they could pick up in the day time, lined east, ground oil-cake, or grains, cabbages, roots, and winter and spring vetches, and tares. Salt, he says, I never gave my sheep, or my lamb, except in case of necessity; and the following way: A small field of oxtails, cut in September, had been so often wetted, that I despairs of his ever being eaten. While it was putting into the rick, I stewed some salt between the layers; the consequence was, that cows and sheep greedily devoured it, scarcely leaving a single blade. (Com. to the Board of Agr. vol. v. p. 503.)

725. The shearing of the sheep is always performed in the month of June, and of the lambs at the end of July. The finer furred lambs need not be shorn till the second season. Washing previously to shearing Dr. Parry disapproves of; because the fleece is so thick, that when thoroughly soaked with water, it is almost impossible to wet the wool, and the skin of the sheep are evidently much incommoded; therefore he recommends cleansing the wool, after being shorn, as in Spain.

726. The product of wool, as the result of Dr. Parry's well conducted experiments, was found to be 14 lbs. 14 oz. per acre, which at 3s. 7d. per acre on land certainly not worth on an average site, (See Cages and sheep of Agricultural Land to the entrance of Lord Somerville's experiments may be considered as of equal, if not more importance than these of Dr. Parry. His Lordship tried crosses with several short-woofled breeds, but was most successful with the South Downs and Ryelaens. Morris Birkebeck, a professional farmer of the first order, found that the fleeces of the first cross between Merinos and South Downs, washed, are to the parent South Downs as five to six in weight, and as three to two in value per pound, and believes that the improvement of the wool may go on, without detriment to the carcases, unless we shall obtain a breed of sheep with Spanish fleeces, and constitutions of the present Southdowns. This must be, he says, the breed for the future.

727. Merino flocks are now established in most districts of the empire, and but few years can elapse before its value to the farmer and the country be practically ascertained and evinced. (See Sir J. Banks to the Honours of Agriculture, Com. B. of Agr. Bath Society's Papers, Dublin Society's Transactions, The Farmer's Magazine, Farmer's Journal. Lord Somerville's and Dr. Parry's Tracts on Wool and Merinos, and various other works.)

Sect. VIII. Anatomy and Physiology of Sheep.

728. The general structure of the sheep resembles that of the ox very intimately. Sheep, however, like the ox, experience considerable variations in size, form, and qualities; resulting from the physical and moral agencies which they become exposed to, under various climates, and, as also, whether fostered by cultivation, or left to the natural operations of nature around them. These circumstances have operated on even the bony base of the machine, as we see in the formations of the three-horned breed (Ovis polycrarta Lin.), natives of the north; in the spiral-horned (O. Strepsiceros Lin.), which inhabit Wallachia; and the long-horned (Capra A'mmon Lin.), which are found in the countries bordering the Mediterranean: and which have been thought to be the parents of the present cultivated British sheep.

729. Cultivation weakens the otherwise inherent aptitude to retain the original stamp of nature; and we find, therefore, that, by these means, the original form of the sheep has submitted to vast alterations. We find, that a few generations of them wholly without horns; and we also find that the bony structure is otherwise subjected to our command, by becoming much more slender, though more compact. Accidents are also laid hold on by man to produce particular forms: thus a breed has been cultivated in America, called the ancon or Peruvian sheep, wholly naked, with crooked and deformed legs; which, by continued breeding from specimens that presented this original accidental deformity, is in the second stock fixed and permanent breed, valuable for their incapacity to wander or climb. (Dought.) The dunkey, or wry-faced breed, is another instance of accidental deformity cultivated into a permanent variety: as the monstrous rump of the Tartarian sheep, and the over-grown tails of the breeds in Turkey, and the Cape of Good Hope, are similar instances in the softer parts of the body.

730. The skeleton of the sheep presents an assemblage of bones, which bears a general resemblance to that of the ox in number and direction. Like him, the head naturally is surmounted by horns springing from the frontal bones. Like him, his front feet are cloven hoofs. The eyelids are not toothed. Like the ox, his external nostril is surrounded by a small cartilaginous disk. His skin is very loose and pliant; the muscles of his back are equal to the ox. His vertebral column is the same as the ox, and his ribs also. The extremities descend on the bony extremities, ending in the bony extremities. His tongue is much the same as that of the ox: large, and covered with thick white papillae. His head, which is as one to two hundredth to the whole body; and his cerebellum to the brain generally, as one to five. The pigment of the eye is of a yellowish green, varying in some forms to a yellow. The viscera of the chest correspond with the ox; and those of the belly also, the stomachs being the same in both, only the rumen of the sheep is a great deal larger. The liver, pancreas, and spine are similar. The penis is taper, vesicular seminiles wanting, and the urogenital parts the same.

731. The wool of the sheep is not a crisped hair; and indeed in some foreign varieties, the outer cover of long hair like that of oxen; while in others, the hair and wool are mixed.

Sect. IX. Diseases of Sheep.

732. The diseases of sheep are numerous; for these animals are now so highly cultivated that they may be regarded in some respects as artificial machines: and thus, as a natural consequence, they are subjected to a variety of artificial defects or maladies.

733. The rot is a popular term among shepherds, and includes within its range diseases widely different. We shall not, therefore, follow the custom of treating the different rots of sheep together; but we shall allow them to fill their natural place in order, according to the plan of the inflammatory and putrid fever, popularly known by the names higham striking, or blood striking; does not differ materially from the same disease in oxen and cows; and is in sheep also sometimes epidemic; appearing by paining, dulness, watery mucus from the nose and eyes; and great redness of all such parts as are usually white.

734. The red water. The inflammatory fever sometimes resolves itself into a universal secretion of serum throughout all the cavities; in which case, after a few days, the lymph tinged with blood will come
away from the nose and mouth in large quantities. Sometimes after death the bloody serum is found suffused throughout the skin as in the blood-striking of skins.

The disease chiefly affects the liver, but it is a diffuse one, and may be said to extend to all the internal organs. The character of this disease, in which it takes on a putrid form. About the third day small variaes appear; sometimes they are rather blisters than spots. The weakness is extremely acute, and the putridity great. This form of the disease is seldom seen with us; but is still known on the Continent, where the pastures are very poor and low, and the general keep meagre.

7349. The treatment of all these in nowise differs from that directed under the inflammatory putrid fever of the ox; the doses of medicine being about a third of what is directed for this disease. Often, symptoms are so similar to those which characterize the pastoral rot in oxen, that it is difficult to separate them. The symptoms of this disease are most strongly marked in the February of 1808, on a farm in the neighbourhood of Streatham; where eleven sheep were attacked almost together, after a very stormy night. They were first affected with a loss of appetite; next with a fixed stool, which was common to every one. After this, they reeled about, fell backwards, and became convulsed.

When seen, they were already dead, whose internal appearances fully confirmed the nature of the disease. The rest recovered by bleeding and drenching, with drenches composed of nitre and tartar emetic. Sometimes the symptoms of pneumonia do not kill immediately, but degenerate into an ulceration of the lungs, which is then called the glanderous rot. This stage is entirely fatal; the others may, by early attention, be combated by judicious treatment, as detailed under the same disease in oxen.

7352. A chronic cough in sheep, when not symptomatic of rot, is always cured by a change of pasturage, particularly into a salt marsh.

7353. Inflammation of the stomach occurs from various causes. A common one arises from eating noxious vegetables; and produces the affections termed vomitings, etc. It is also caused by certain worms, the latter is always attended with the discharge of castor oil; while the former usually yields to half an ounce of oil of turpentine, beaten up with the yolk of an egg. Some herbs, as A tropa Belladonna, when eaten produce spasmodic affections, which are capable of being relieved by the watery solution of aloes (1 Part Aloes, 2 Part Water). The doses of two or three ounces is useful. Daffy’s elixir we also have it well known to have great effect.

7354. The hore, blast, or wind colic. Sheep are as liable to be distended with an enormous collection of wind, or gas, as are oxen, and are relieved by these medicines as are applicable for directed for oxen. (695.)

A wind colic will also sometimes affect sheep from the quality of what they eat; it is best relieved by an ounce of castor or salt oil with an ounce of gin.

7355. Internal leprosies are liver affections arising from fever settling in that organ; or from obstructed bile irritating it. Sometimes there are great marks of fever; and at others more of putridity; according to which, treat as may be gathered from ox patholog y.

7356. Jaundice also now and then occurs in sheep, and is a disease referred to that disease in oxen, where the same remedies are applicable as are directed for oxen. (692.)

7357. Inflammation of the lungs, or bronchitis, gulf scours, and scrofulous affections of the lungs, or bronchitis, are all affections brought on by sudden changes of temperature, or of undue moisture acting with cold pasturage. It is often seen in sultry autumns; and, by a judicious observer, has been said to be peculiarly frequent in hogs or sheep of over three years. Like other diseases of this nature, it is frequently prevalent, and when recommended by observant practitioners, it may be supposed to arise from a previous costive state, to remove the affected (as is practised by the shephard-masters of Scotland) into turnips. The general medical treatment does not differ from ox braxy. (681.)

7358. Scouring is the diarrhoea of sheep, and in very hot weather soon carries them off. It should be early attended to, by abracing the affected, and housing them. The treatment is seen under diarrhoea of oxen (688.), which it closely resembles.

7359. Pinning, tag, belt, break-shake. The two former are only the adhesion of the tail to the wool, and the excoriation brought on by diarrhoea; the latter is the diarrhoea itself, known to some by this term.

7361. The rot in sheep is also called great rot, and hydroptic rot, etc.; but it is more popularly known by the single term of rot. It is also known in the military as typhus, in Friesia, hypeatic, and typhus; and, in other countries, under the term of scrofulous, the sheep are infected with an ulcerating, fistulous disease, which is most commonly known as scrofulous, to be the same disease, which commonly is called morbus alimentarius. Some of the latter have already been seen in the country, and it is difficult to separate their effects. It is not, perhaps, the actual quantity of water immediately received by land, but the capacity of that land to retain the moisture, which makes it particularly of a rotting quality.

7362. Several affections are sufficiently familiar to persons about sheep. They first lose flesh, and what remains is flabby and pale; they also lose their vivacity. The naked parts, as the lips, tongue, etc., look livid, and are alternately hot and cold in the advanced stages. The eyes look sad and glassy, the breath is fetid, the urine small in quantity and high-coloured, and the bowels are at one time constipated and at others loose. The pelt will come off on the slightest pull in almost all cases. The disease has different degrees of rapidity, but is always fatal at last. This difference in degree occasions some rotted sheep to thrive well under its progress to a certain stage, and so remain in health when the smallpox, colic, or other diseases fall off on the same sheep. Some have their pelt come off in the rest. Some of these diseases under this crisis of decension, as it is called, and kill their sheep for market in the immediate nick of time with no loss. In these cases, no signs of the disease are to be traced by ordinary inspectors, but the existence of the flakes, and still more, a certain state of liver and of its secretions, are characteristic marks to the wary and experienced.

7363. The treatment of rot is seldom successful unless it is early commenced, or when of a mild nature; a total change of food is the first indication, and of that the usual staples; but; for the kind of disease, the meals of wheat, barley, oats, peas, beans, etc. Carrots have done good much with these;
broom, burnet, elder, and melilot, as diuretics, have also been recommended; but it is necessary to observe that these are all very strong emetics, but in the latter stages of the complaint. As long as the liver is not wholly disorganised, the cure may be hoped by a simple removal of the cause, which has been shown to be a variable temperature, with excessive moisture of pasture, which may also be aided by such remedies as are the habit of the biliary system, salt, or wine, if good; salt may also be given in the water. Salt appears the principal ingredient in Flesh's patent restorative for sheep; for it states it to be composed of turpentine, sal ammoniac, turmeric, quicksilver, brimstone, salt, opium, alkaest root, bark, antimony, camphor, and oil of vitriol. Salts have the decided action of opening the pores of the skin, and the water can be used with safety to try useful but the salt. In the more advanced stages of the disease, when the liver has become materially affected, it is prudent to rub the belly of each sheep with half a drachm of mercurial ointment every other day for a week: give also the following, every morning.—

1. A tincture of aloe, half an ounce; decoction of willow bark, four ounces; nitric acid, two grains.

2. The pot rot, hunger rot, or naked disease, is a variety of the former, but with this difference, that whereas the liver in the hydroptic case. The principal affected glands are the mesenteric glands which are always swollen and obstructed, and from thence arises the emaciated and unhealthy state of all the rest, by which the wool becomes incapable of receiving nutrient, and falls off, leaving the body bare, and in the last stages the teeth and horns also loosen. In fact, a diseased sheep is very much different from that of this malady, and a contrary course of treatment is the best remedy when the disease has not gone on too long.

3. The scab, shub, ray, or rubbers, are sometimes erysipeloid eruptions, and sometimes they are peotic or mangy ones. In the former instance they are universal and very red, occasioning a great heat and itching, and are then called the rubbers: in such cases, nitre administered quickly relieves, with change of foot. The erupitive scab is seldom cured without an external application; either of those directed for mange, lowered to half the strength, will relieve it at once. (See Vet. Pharmac.)

4. Foot rot. Sheep have a secretory outlet between the claws peculiar to them, which is liable to become obstructed; for which soaking in warm water and afterwards wrapping up the foot, having first dressed it with tar, is sufficient. The feet of sheep are also sometimes injured by long travelling, when the same treatment provides proper. The mortality from this rot is considerable. A serious foot rot is that in which a continued series of humid weather, which predisposes the feet to this injury. In others it appears to be both epidemic and endemic, and has been thought contagious. When the season has been unfavourable, house and soil under cover. The medical treatment is that of removing all discharges and sores, and interfering with the exterior exposure. The following application (8-9 parts of tar, and one of oil of turpentine; which having mixed, one part of muriatic acid, known as spirit of salt, is to be added slowly, to which are afterwards added four parts of blue vitriol, with which dress the affected foot). (Journ. de Med. Vet. et Comp.)

5. Staggers, gid, turnicis, goggles, worm under the horn, sturdy, watery head, and pBuzz, are all popular terms for hydatids, or an animal now known as the Teuchin sheep, which, by some unaccountable means, have been infected with one or more parasites of the body. The size varies from the smallest speck to that of a pigeon's egg, and the sheep it attacks are usually under two years old. These animals are likewise occasionally found in all the natural cavities of the body.

6. The appearances of cerebral hydatids are, stupidity, a disposition to sit on the rump, to turn to one side, and to incline the head to the same while at rest. The eyes glare, and from oval the pupils become round. An accurate examination will now usually discover some softness of the skull, generally on the contrary side to that on which the animal hangs the head: when no softness of the skull is discernible, the hydatid usually exists in some of its ventricles, and the destruction of the sheep is certain and quick, from the greater disturbance to the functions of the brain; but when it is situated on the surface, it sometimes requires months to destroy; an absorption of the bone taking place as the hydatid increases, which produces the thinness in the skull opposite to the affected part.

7. This disease is not incurable, as has been supposed, but it is only relieved by a manual operation. In France it has been successfully treated by the application of two sharp needles inserted in the surface of the brain; the principal nicety of which is in penetrating the hydatid with the hot iron without wounding the brain itself. In England, some shepherds are very dexterous in rearing, which they do by thrusting a sharp instrument into the nostril till it rests against the tooth, and the mouth is used to pull the head. The hydatid is then extracted, by the introduction of a trephine or even a knife, opposite to the softened part, and extract the hydatid, if possible, whole, which a little care will effect, by drawing it away with a blunt pincer, gently moving it from side to side, till the point of it enters into the brain cavity. Tapping is merely letting out the fluid contents of the brain; but if the sand be not thrust to the far, the sheep is not injured: to avoid which, it is passed obliquely. A well hardened gimlet is a very proper instrument, with which the skull is easily penetrated, and an opening by the twisting of the instrument is made, sufficiently large in the hydatid itself, to discharge its contents, which is all that is sufficient to ensure its destruction, and which, if no other exists, is followed by immediate recovery.

8. French author states, that when he fed his sheep on copper he found less staggerers than at any other time.

9. Frontal worms. Sheep are observed to gather together, with their noses thrust inwards to avoid the attack of the Vaucoo vco, or fly, that lays its eggs on the inner margin of the nose, which having become hatchet, the larva creep up into the frontal and maxillary sinuses, to the torment of the sheep, and sometimes to their speedy destruction. The anterior shepherds trepan an opening into these cavities, and extract them out with a forcible removal; but our shepherds have not succeeded in that operation.

10. Fluke worms are a parasite animal, found in the biliary sinuses, not only of the sheep, but of the horse, ass, goat, deer, etc., and whose existence is rather a consequence than a cause of morbidity.

11. Sheep, in Guernsey (towards the south of France described by Mr. Hogg, the Ettrick shepherd), in a recent number of the Quarterly Journal of Agriculture, xi. p. 691. He says, "It is most fatal in a season of drought; and June and September are the most deadly months. If ever a farmer perceives a flock on such a farm having a flushed appearance of more than the ordinary state of rapid vegetation, he is good to know that the sheep are diseased; and in such cases, he will find them lying, hanging their ears, running, and looking at him like so many condemned criminals. As the disease proceeds the hair on the animal's face becomes dry, the wool assumes a bluish cast; and if the sheep have been long enough in possession of changing the appearance, all those affected will fall in the course of a month." (Quar. Journal, Agr. Highl. Soc. vol. ii. No. XI.)

12. The diseases of lambs are principally midgestive, producing sometimes colic, which is relieved as in sheep, and sometimes diarrhoea, to be speedily cured by administering dry emetics. The most common eruptions on the rump, gradually extending along the side, and when it becomes more universal, it usually destroys. The cure consists in giving early drinks of half a drachm of cream of tartar, and one drachm of sulphur, in four ounces of ammoniac solution. And also with mild mercurial emetics. Wherever the reins are affected, in quicksilver or in pot, in wet seasons, become paralytic; bathe in warm water, hand-rub and house, giving milk and bean meal.
The Swine.—Sís Scrofa L. Cochon, Fr.; Schwein, Ger.; Puercos, Span.; and Porco, Ital.

7274. Of swine there are several species, but none in general domestication, or much used as food when taken wild, excepting the common sort, which includes the wild hog or wild boar, the original stock of our domestic breed, the European hog, and the Chinese hog.

7275. The common hog is found either in a wild or domestic state, in almost all the temperate parts of Europe and Asia; but it is not met with in the most northern parts of these continents. It is found in most parts of India. On many of the Low Countries, that the wild boar was formerly a native of this country, and hunted from the middle of November to the beginning of December; and it is asserted by Fitz-Stephens, that the vast forest which in his time grew on the north side of London, was the retreat of stags, wild bears, and boars.

7276. The wild boar is still found in the forests of Germany, and in other parts of the Continent; and although now extinct in Britain, appears from ancient paintings (fig. 898) to have been hunted by our ancestors. It feeds upon roots, acorns, and other vegetables; it is generally as large as the domestic hog, and is either dark grey or blackish, when full grown, and pale red or rusty brown when young. Between the bristles, next the skin, is a finer or softer hair of a woolly or curly nature. The snout is somewhat longer in proportion than that of the domestic animal; but the principal difference is, in the superior length and size of the tusks, which are often several inches long, and capable of inflicting the most severe and fatal wounds. The hunting of the wild boar forms one of the principal amusements of the great in some parts of Germany, Poland, &c., and is a chase of some difficulty and danger, not on account of the swiftness, but the ferocity of the animal. With a tallow, which has not passed the third year, are called by the hunters beasts of company, because previous to that age they do not separate, but follow their common parent. They never wander alone till they have acquired sufficient strength to resist the attacks of the wolf. These animals, when they have young, form themselves into flocks, and it is upon this account that their safety depends. When attacked, the largest and strongest force the enemy, and by pressing all round against the weaker, force them into the centre.

7277. Of the tame hog, white is the most general colour; but other colours are often intermixed in various proportions. In some respects, both domestic and foreign hogs seem to form an intermediate link between the whole and the cloven-footed animals; in others he seems to occupy the same rank between the cloven-footed and digitated. Destitute of horns; furnished with teeth in both jaws; with only one stomach; incapable of rumination; and hath at one birth a numerous progeny; the union of these faculties confers on the hog an extraordinary peculiarity of character. He does not, like other animals, shed his fore teeth and put forth a second set, but retains his first set through life.

7278. Hogs seem to enjoy none of the powers of sensation in eminent perfection. They are said to hear distant sounds; and the wild boar distinguishes the scent of the hunter and his dogs, long before they can approach him. But so imperfect is their feeling, that they suffer mice to burrow in the fat of their lumps without discovering any uneasiness, or appearing even to notice it. In their taste they show a singular degree of caprice. In the choice of herbs they are more particular than any other animal, yet devour the most nauseous and putrid carrion with more voracity than any beast of prey. At times they do not scruple to eat their own young; they will even mangle infants out of desperate voracity.

7279. Hogs are remarkable for the smallness of their eyes: hence a person whose eyes are very diminutive, and deep sunk in his head, is said to be pig-eyed. The form of the hog is indelicate, and his carriage is equally mean as his manners. His unwieldy shape renders him too incapable of swiftness and sprightliness, than he is of gracefulness and motion. His appearance is always stupid and uncouth. He delights to bask in the sun, and to wallow in the mire. An approaching storm seems to affect his feelings in a very singular manner. On such an occasion, he runs about in a frantic state, and utters loud shrieks of horror. Hogs are infested with lice, and are subject to many disorders, such as the scurvy, scab, and scrofula. The sow brings forth in the beginning of the fifth month after conception, and she has often twost in a litter. She generally produces a numerous progeny at a birth; but her first litter is less numerous than those that follow. Hogs, when suffered to see the natural term of life, live from fifteen to thirty years. Their size and strength continue to improve till they are five or six years old.

7280. Tame hogs are often very troublesome in cultivated grounds, ploughing them up with their snouts, and thus entirely frustrating the labours of the agriculturist. Worms, the wild carrot, and other roots, are the objects of their search. The wild boar having a longer and stronger snout than the domestic variety, digs deeper, and continues his burrow nearly in a straight line. The inhabitants of America find the hog very beneficial in clearing their lands of rattlesnakes and other serpents, upon which he constantly preys, without apparently suffering any injury.

7281. The hog, in a very considerable degree, beneficial to mankind. His flesh is pleasant, substantial, and nutritious. It affords numberless materials for the table of the epicure; among these is brown, which seems peculiar to England. Pork takes salt better than the flesh of any animal, and is, in consequence, preserved longer, and always makes an important article in naval stores. The lord of the hog is essential to the cook and confectioner; it is used in various medical preparations, and is compounded by the perfumer into pomatumata. The bristles are made into brushes, and are, moreover, of great use to the shoemaker.

7282. The hog in British farming is in general viewed as a subordinate species of live stock, and chiefly valuable as consuming what would otherwise be lost. There are, however, swine husbandmen who keep large herds to advantage, especially malters, brewers, distillers, to whom the flesh of hogs is almost preserved longer, and always makes an important article in naval stores. The lord of the hog is essential to the cook and confectioner; it is used in various medical preparations, and is compounded by the perfumer into pomatumata. The bristles are made into brushes, and are, moreover, of great use to the shoemaker.

7283. In British farming is in general viewed as a subordinate species of live stock, and chiefly valuable as consuming what would otherwise be lost. There are, however, swine husbandmen who keep large herds to advantage, especially malters, brewers, distillers, to whom the flesh of hogs is almost preserved longer, and always makes an important article in naval stores. The lord of the hog is essential to the cook and confectioner; it is used in various medical preparations, and is compounded by the perfumer into pomatumata. The bristles are made into brushes, and are, moreover, of great use to the shoemaker.
meat, and their culture can never be so much depended on by the general farmer as that of cattle or sheep. A writer in the Farmer's Magazine observes, that the swine are the only variety of graminivorous animals that can be fed upon the offal of grain, or such articles as would otherwise go to waste about a farm-stead. Since the erection of threshing machines, a much greater quantity of light grain is beat from the straw, than was gained when the flail was employed. To use this extra quantity to advantage becomes an important concern to the occupiers of land; and this writer thinks that the using of it in raising and supporting swine is by far the most profitable mode of consuming an article, which, in other respects, is comparatively of little value.

Sect. I. Varieties of the Common Hog.

The domesticated European variety of the common hog (fig. 899.) is too well known to require any description.

The Chinese hog (fig. 900.) is distinguished from the common, by having the upper part of its body almost bare, its belly hanging nearly to the ground; its legs are very short, and its tail still more disproportionately short. The flesh of this variety is white and more delicate. The colour is commonly a dark grey.

It abounds in China, and is diffused through New Guinea, and many islands in the South Sea. The New Hebrides, the Marquesas, the Friendly and the Society Islands, possess this animal, and cultivate it with great care, as it is almost the only domestic animal of which they can boast. The varieties of hog cultivated in Britain are partly the result of climate and keep in the European variety, and partly the effects of crossing with the Chinese. At the same time, it is only in the more distant districts of some parts of the country, that has been paid to this animal, as to give rise to any accurate distinction of breeds; and nowhere has it received any considerable portion of that care in breeding, which has been so advantageously employed on the other animals of which we have treated. Yet, among none of the varieties of animals is there so great a difference as among the breeds of this species, in regard to that return for the consumption of a given quantity of food. Some races can with difficulty be made fat, even at an advanced age, though fed from the trough with abundance of such food as would fatten any other animal; while others contrive to raise a valuable carcass out of materials on which no other creature could subsist.

The Chinese race, according to Culley, has been subdivided into seven varieties or more; and it would be easy to point out twice the number of as prominent distinctions among the sorts in the third class. But such an affectation of accuracy as is useless as it would be tedious. One general form, approaching to that of other animals kept for their carouse, ought certainly to be preferred; and the size, which is the other distinguishing characteristic, must be chosen with a view to the food provided for their maintenance, and not because it is possible to raise the individuals to a great, and probably, unequal, weight. The fineness of the body, and, though also deep, form of the chest, denote in this, as in the other species, a disposition to make fat with a moderate consumption of food; and while it may be advisable to prefer the larger breeds in those places where bacon and fitches are in most demand, the smaller breeds, in all respects, the most esteemed for hanging, and are, beyond all doubt, most profitable to those farmers who allow them little else than the range of the farm-yard and the offals of the kitchen.

The Berkshire breed (fig. 901.) is distinguished by being in general of a tawny, white, and reddish colour; spotted with black; large ears hanging over the eyes; thick, close, and well made in the body; legs short; small in the bone; having a disposition to fatten quickly; and when well fed, the flesh is fine. Berkshire has been long famous for its breed of swine, which, as it now stands, is, in the third class, in point of size, excellent in all respects, but particularly as a cross for heavy, slow-rearing sorts. It has extended itself from the district from which it took its name over the whole of the isle; is the sort mostly fattened at the distilleries; feeds to a great weight; is good for either pork or bacon; and is supposed by many to be the best hands in respect to their nature and the food on which they are fed.

The Hampshire breed (fig. 902.) are large, longer in the body and neck, but not of so compact a form as the Berkshire; they are mostly of a white colour, or spotted, and are well disposed to fatten, coming up to a great weight when properly managed in respect to food. Lawrence says they are generally dark spotted, some black, of a longer and fatter make than those of Berks, ears more pointed, head long and sharp, and are excellent. They are not so well formed as those of Berks, or equal to them in their disposition to fatten, or to be supported on such cheap food. The standard colour of this breed is white, or brindled; Shropshire has long bred stores for the supply of the London feeders, and these farmers, who thus turn their clovers to the most profitable account.

The Gloucestershire breed is likewise a larger breed, but inferior to either of the above, being tall and long in shape, and by no means so well formed. The colour is white. It has two wattles hanging from the throat.

The Herefordshire breed (fig. 903.) is also a large useful breed, but perhaps without possessing any advantage over those that have been described above.

The Jersey breed is a large kind of swine, of which the author of the Survey of Middlesex says is the largest in the island, met with at the village of that name, on the borders of Sussex and Surrey. They feed on an extraordinary size, and weigh, at two years old, nearly double or triple the usual weight of other sorts of hogs of that age. As large breeds pay the farmers best in many cases, such a breed deserves to be attended to in the system of hog management.

The large spotted Woburn breed is a breed introduced by the late Duke of Bedford, being large in size and of various colours. It is a hard, well formed, prolific sort, rising quickly to a large weight.
The Williabred breed is a long-bodied, low hog, hollow about the shoulder, and high on the rump, middling large pointed ears, round bone, light in colour.

BREEDING the Berkshire, because they are smaller and of superior quality than the Northumberland, they are more numerous in many parts of the country, many of them having curled and woolly coats. They are middle-sized, quick-proving pigs. Their bristles are short, upright, and shaggy, in various patterns, rather a hair, and white, smooth, or not, generally an inferior kind, which would be to the interest of the great corn county to improve; they are, however, of a thin-skinned, quick-proving kind. But in the vicinity of Lynn, and in general on the Lincoln side of the county, there is a larger spotted variety of very good form and quality, which should be encouraged.

This is a small, delicate, white pig, which has for many years had great repute; and at this time there is not only a strong prejudice in the county, in their own country, but in the whole of it. They are shorter and more woolly, or Norfolk, and by their dish-face, and pendent belly, it may be supposed that the variety proceeded originally from the white Chinese. Some of the Suffolks are very handsome, and very regularly shaped.

The Essex breed are up-cared, with long sharp heads, round ears, and generally high upon the leg, bone not large, generally white, or black as hair, quick feeders, but great consumers, and of an unprofitable disposition.

The small, white, English breed is met with in many districts; it has a light colour, thick, and dirty, scaly coat, and well formed head short in the leg; the head and neck well formed, and the ears slouching a little downwards. It is well disposed to fatness, and perfectly hardy. It prevails much in the northern districts.

This is a useful sort of the smaller kind of hogs, partly in its nature, and of considerably weight in proportion to its size.

There are many other varieties and subvarieties in England which it is unnecessary to notice here. Donaldson remarks, that the Berkshire hogs are the truest; but that it is most probably from the Berkshire stock that the greatest number of the varieties of the country have sprung.

Of the Highland breeds, that of the Hebrides, supposed by Dr. Walker to be the original, is of the smallest size, neither white nor yellow, but of a uniform grey colour, and shaggy, with long hair and ears; they are on the hills like sheep; their sole food is herbage and roots, and on these they live the whole year round, without shelter, and without receiving any other sustenance. In autumn, when they are in the best order, their meat is excellent, and without any artificial feeding; but when driven to the low grounds, it is of a considerable bulk. [Walker's Hebrides, vol. ii. p. 17.]

In the Orkney islands they are commonly of a dark red or nearly black colour, and have long bristles, with a sort of coarse wool beneath them.

The old Irish breed are a long-legged, thin-sided, lank, haggard, unprofitable sort of swine; but when they have been crossed with the Berkshire, they are considerably improved.

Sect. II. BREEDING AND REARING OF SWINE.

In the breeding of swine, whatever be the variety, the most perfect and best formed boar and sow should be chosen, and a due regard paid to their age, time of copulation, period of gestation, farrowing, castrating or spaying, and weaning.

In choosing the boar and sow, regard must be had to their size, as well as proportion of their parts. Where food is abundant, or the object of the progeny the production of bacon and fitches, the larger breed is to be preferred; but where food is scarce, or uncertain, as in the case of the cottage's stock, or rearing for suckled pork, fresh pork, or pickled pork, the smaller breeds, as the Berkshire, are to be preferred. A breeding sow ought to have a large capacious belly, and not to be too much inclined to obesity. To check this tendency, some allow them to breed five times in two years.

The boar should not be less than a year, as he will then be at his full growth; nor that of the female less than ten months. They may be used in breeding for three or five years, and then bred off for the shambles.

The period of gestation in swine is about four months, so that two litters may be easily produced in a year, five in two years, or ten in four years.

The best times for copulation are November and May; but that the progeny are brought forth in mild weather, and when green food is to be had. They should not be allowed to farrow in winter, as young pigs are difficult to be kept alive, and in very cold a time when food is scarce, as is generally the case upon corn farms in summer, if the stock of them is large. When the object is suckled pigs for the shambles, copulation should be so contrived as to produce Pietrain pigs in all seasons.

The usual produce is from about eight to ten or twelve pigs in the large but more in the smaller breeds, which in general bring the greatest number, and the most early. Twenty swine are estimated to bring at an average seven pigs and a half each for their first litter; but the number varies much, and many young pigs are lost soon after their birth by the wantonness of their dam, and by casualties, to which they are more exposed than most other young animals.

The pregnant sow should be separated from her herd some time before she is expected to farrow, and likewise the sows of dry short meat. Too much quantity of dry short meat is improper, both at the time of farrowing, and for a week or two afterwards, as the pigs are apt to nestle beneath it and be imperceptible by the sow, and are thus in danger of being smothered when she lies down. A breeding sow should be well fed, particularly when nursing; and it is advantageous early to accustom the pigs to feed from common troughs filled with meal or other food. Such of them as are not kept for breeding are usually castrated or spayed when about a month old, and the whole may be weaned at the end of six or seven weeks.

The condition allowed to growing pigs varies in almost every case upon the circumstances of their owners; for, as already observed, it is a doubtful point whether swine will pay when all their food both in rearing and fattening is to be purchased. The cottager's pig must be contented with the scanty offals of his kitchen and of his dairy, the produce generally of a single cow; towards the end of autumn all their potatoes are added for the purpose of preparing it for the slaughter, and perhaps a little meal is mixed with boiled potatoes for a week or two before. Such pigs, however, often thrive amazingly, make themselves moderately fat, and form a most valuable addition to the winter stores of their owners. In the south-eastern
counties of Scotland, the hinds or married ploughmen are commonly allowed to keep a pig each, which lends them, and frequently their families, a portion of their corn, to be dressed in the winter, and from which they derive some advantage. Near woods, copses, and other similar spots, as well as some roots and vermin, afford excellent nourishment. Many corn farms, the chief, and not unfrequently the only, dependence of swine is on the straw-yards. The swineherd and his family, every man his own, have the straw-yards, and to them the swine are driven, to be fattened, in the winter, and fed through the summer and autumn months, and the like extent of ground for turnips and yams during the winter and spring months, this stock of swine may be amply supported.

7316. Upon a tillage farm consisting of three hundred acres, whereof two hundred are kept under the plough, he is of opinion that a considerable sum may be annually gained from keeping swine, were the management arranged in a systematic manner. One main advantage of such a branch of rural economy arises from the little or no capital being required to carry it on, while the trouble and outlay attending it scarcely deserve notice. With the addition of one acre of broad bean, the summer and autumn months, and the like extent of ground for turnips and yams during the winter and spring months, this stock of swine may be amply supported.

7317. A single sow kept for a farm of the size mentioned, and their produce reared by the farmer, it may be calculated that forty swine, weighing seven or eight stone each, would be annually fed off, in the month of January and February each year, the time when pork is most in demand. That such a number of swine can be supported and fed upon the odds of a three-hundred-acre farm, and the other provisions specified, will be concisely proved.

7318. The breeds he recommends are the hardy smaller sized varieties; because he has found that such breeds will thrive and grow fat where larger and finer breeds would starve.

7319. The object of management is, that a boar and two good sows of a proper age should constantly be kept, and that one young sow shall annually be reared, in order to supply the others when they pass maturity. He would cast off the oldest sows, i.e. feed them when they arrive at three years of age, which, of course, would cause four sows to be in hand at one time. These annuals would produce more than the young sows required for the breeding of the herd, and should be sold as they are weaned, there being a regular and steady demand in most parts of the country for young pigs. He has for a number of years kept a stock of swine in the way recommended. They go at large in the court or yard belonging to the farm, and receive a feeding of oiled grain in the morning, and of yams or turnips in the evening; and the meat fed in this way has constantly drawn the highest price. They get also the dish-washings of the house, any milk or whey that remains unconsumed, and have the dunghill to roam upon, where perhaps more food is to be gathered, especially if the hogs are fed upon unbroken grain, than is commonly supposed. Under this system of management, in the latter end of summer and the harvest months is the critical period for carrying on a stock of swine. During these months little threshing goes forward, and horses seldom receive any corn for aliment; hence all that can be conscientiously attempted is to keep the animals in a growing state, and prepare them for fattening cleverly, when food of a more nutritious quality can be procured. Clover and tares will do this effectually, the last particularly so when in a podded state. Turnips can also be got by the end of September; and it must be recollected, that through the summer months a large quantity of oiled grain and milk and whey can be given, upon which swine will thrive heartily. He does not know a more beneficial stock upon a farm than swine, so long as the quantity kept is in proportion to the extent of oills about the premises. The other articles recommended are merely meant to render the consumption of oills more beneficial, to carry the swine through those periods when oills are scarce. The charge of oills at present is so great, that the benefit gained by the dunghill will much more than compensate the expenses incurred. To make as much profit from cattle or sheep requires a great advance of money; but in the article of swine hardly any is necessary, while the most part of the articles consumed cannot, in any other way, be converted to such beneficial purposes.

7320. In fattening for bacon and hitches, the larger breeds are chosen; and in breweries, distilleries, oileries, and dairies, fed on grains, oil-cake, and milk; but where arable farmers keep swine of this description, as is the practice in some of the western counties, the method is to rear chiefly on raw potatoes and Swedish turnips, and to fattten on these roots, boiled or prepared by steam, with a mixture of oat, barley, or bean and pea meal. Their troughs should be often replenished with a small quantity of food at a time, and kept always clean, and their food changed occasionally with seasonable variety. If proper care be taken, says a late writer, a feeding pig should not consume more than six Winchester bushels of oats made into meal. It ought to be shielded before it is ground, the same as for family use, but need not be sifted. (Henderson’s Treatise on Swine, p. 26.)

7321. The object of fattening pigs, all agree, is requisite is to keep the mother well lodged and nourished. Weaned pigs when to be fattened are kept constantly on whey, or skim-milk or buttermilk, with frequently an addition of peas or beans, or barley-meal. Such good keeping not only makes them increase rapidly in weight, but they will fatten at an early age. They may be sent to the butcher at different ages, and under different names; as pigs when a few weeks old; as porkers at the age of five or six months; and as full grown hogs from eighteen months to two years old. The young pigs are commonly roasted whole; the porkers are used for fresh or pickled pork; and the full grown hogs are either sold as bacon, part converted into hams and bacon. The demand for porkers, which the Locoine or tares, for the great, and which continues almost throughout the year, is chiefly supplied from the dairies within reach of that metropolis.

**Sect. III. Fattening of Swine.**

*7315. The following system of rearing and fattening swine on an arable farm is recommended by a writer in the Farmer’s Magazine.*

7316. Upon a tillage farm consisting of three hundred acres, whereof two hundred are kept under the plough, he is of opinion that a considerable sum may be annually gained from keeping swine, were the management arranged in a systematic manner. One main advantage of such a branch of rural economy arises from the little or no capital being required to carry it on, while the trouble and outlay attending it scarcely deserve notice. With the addition of one acre of broad bean, the summer and autumn months, and the like extent of ground for turnips and yams during the winter and spring months, this stock of swine may be amply supported.

7317. A single sow kept for a farm of the size mentioned, and their produce reared by the farmer, it may be calculated that forty swine, weighing seven or eight stone each, would be annually fed off, in the month of January and February each year, the time when pork is most in demand. That such a number of swine can be supported and fed upon the odds of a three-hundred-acre farm, and the other provisions specified, will be concisely proved.

7318. The breeds he recommends are the hardy smaller sized varieties; because he has found that such breeds will thrive and grow fat where larger and finer breeds would starve.

7319. The object of management is, that a boar and two good sows of a proper age should constantly be kept, and that one young sow shall annually be reared, in order to supply the others when they pass maturity. He would cast off the oldest sows, i.e. feed them when they arrive at three years of age, which, of course, would cause four sows to be in hand at one time. These annuals would produce more than the young sows required for the breeding of the herd, and should be sold as they are weaned, there being a regular and steady demand in most parts of the country for young pigs. He has for a number of years kept a stock of swine in the way recommended. They go at large in the court or yard belonging to the farm, and receive a feeding of oiled grain in the morning, and of yams or turnips in the evening; and the meat fed in this way has constantly drawn the highest price. They get also the dish-washings of the house, any milk or whey that remains unconsumed, and have the dunghill to roam upon, where perhaps more food is to be gathered, especially if the hogs are fed upon unbroken grain, than is commonly supposed. Under this system of management, in the latter end of summer and the harvest months is the critical period for carrying on a stock of swine. During these months little threshing goes forward, and horses seldom receive any corn for aliment; hence all that can be conscientiously attempted is to keep the animals in a growing state, and prepare them for fattening cleverly, when food of a more nutritious quality can be procured. Clover and tares will do this effectually, the last particularly so when in a podded state. Turnips can also be got by the end of September; and it must be recollected, that through the summer months a large quantity of oiled grain and milk and whey can be given, upon which swine will thrive heartily. He does not know a more beneficial stock upon a farm than swine, so long as the quantity kept is in proportion to the extent of oills about the premises. The other articles recommended are merely meant to render the consumption of oills more beneficial, to carry the swine through those periods when oills are scarce. The charge of oills at present is so great, that the benefit gained by the dunghill will much more than compensate the expenses incurred. To make as much profit from cattle or sheep requires a great advance of money; but in the article of swine hardly any is necessary, while the most part of the articles consumed cannot, in any other way, be converted to such beneficial purposes.

7320. In fattening for bacon and hitches, the larger breeds are chosen; and in breweries, distilleries, oileries, and dairies, fed on grains, oil-cake, and milk; but where arable farmers keep swine of this description, as is the practice in some of the western counties, the method is to rear chiefly on raw potatoes and Swedish turnips, and to fatten on these roots, boiled or prepared by steam, with a mixture of oat, barley, or bean and pea meal. Their troughs should be often replenished with a small quantity of food at a time, and kept always clean, and their food changed occasionally with seasonable variety. If proper care be taken, says a late writer, a feeding pig should not consume more than six Winchester bushels of oats made into meal. It ought to be shielded before it is ground, the same as for family use, but need not be sifted. (Henderson’s Treatise on Swine, p. 26.)

7321. The object of fattening pigs, all agree, is requisite is to keep the mother well lodged and nourished. Weaned pigs when to be fattened are kept constantly on whey, or skim-milk or buttermilk, with frequently an addition of peas or beans, or barley-meal. Such good keeping not only makes them increase rapidly in weight, but they will fatten at an early age. They may be sent to the butcher at different ages, and under different names; as pigs when a few weeks old; as porkers at the age of five or six months; and as full grown hogs from eighteen months to two years old. The young pigs are commonly roasted whole; the porkers are used for fresh or pickled pork; and the full grown hogs are either sold as bacon, part converted into hams and bacon. The demand for porkers, which the Locoine or tares, for the great, and which continues almost throughout the year, is chiefly supplied from the dairies within reach of that metropolis.

**Sect. IV. Curing of Pork and Bacon.**

*7322. The curing or pickling of pork is carried on to a considerable extent at many of our sea-port towns.*
of the carcass has hung all night, lay it upon a strong table, or bench, upon its back; cut off the head close by the ears, and cut the hinder feet so far below the hough as will not disfigure the hams, and leave plenty of them to hang them by. Take a cleaving knife, and if necessary, a hack, and divide the carcass up the middle of the backbone, laying it in two equal halves: then cut the ham from the side by the second joint of the back-bone, which will appear dividing the carcass; then dress the ham, by paring a little off the shank or shank-foot, so as to shape it, and save the marrow, and laying off surplus fat. The boner will next take off the sharp edge along the back-bone with a board and malt, and slice off the first rib next the shoulder, where he will perceive a bloody vein, which he must take out; for if it is left in, that part is apt to spoil. The corners must be squared off where the ham was cut out.

In killing a number of swine, what sides you may have dressed the first day lay upon some flags or boards, piling them up across each other, and giving each pitch a powdering of saltpetre, and then covering it with salt; proceed in the same manner with the hams, by themselves, and do not give them a little salt-cure, as it opens the pores of the flesh to receive the salt, and besides, gives the ham a pleasant flavour, and makes it more juicy. Let them lie in this state about a week, then turn those on the top underneath, giving them a fresh salting; after lying two or three weeks longer, they may be hung up to dry in some chimney, or smoke-house; or, if the curer chooses, he may turn them over again without giving them any more salt, in which state they may lie for a month or two without catching any harm, until he has convenience for drying them.

Henderson practised for many years the custom of carting his hams and hams through the country to farm-houses, and used to hang them in their chimneys and other parts of the house to dry; some seasons, to the amount of six hundred carcasses: this plan he soon found was attended with a number of inconveniences, and therefore he invented a smoking-house. Henderson’s smoking-house is about twelve feet square, and the walls about seven feet high: one of these huts requires six joints across, one close to each wall, the other four laid asunder, at proper distances. To receive five rows of flitches, they must be laid in the top of the wall; a piece of wood strong enough to bear the weight of one flitch of bacon must be fixed across the belly end of the flitch, by two strings, as the neck end must hang down below the piece of wood in no case longer than the flitch itself, so that each end may rest upon a beam; they may be put so near to each other as not to touch; the width of it will hold twenty-four flitches in a row, and there will be five rows, which will contain one hundred and twenty flitches; as many hams may be hung at the same time above the flitches conformed in the best manner we can. The lower end of the flitches will be within two and a half or three feet of the floor, which must be covered five or six inches thick with sawdust, and must be kindled at two different sides; it will burn, but not cause any flame to injure the bacon. The door must be kept close, and the hut must not be in a small hole in the roof, or that part of the roof next to it, must be ready to pack up in a hoghead, to send off in eight or ten days, or a little longer, if required, with very little loss of weight. After the bacon is salted, it may lie in the salt-house as described, until an order is received, then immediately hang it up to dry. Henderson found this smoking-house to be a great saving, not only in the expense and trouble of employing men to cart and hang it through the country, but it did not lose nearly so much weight by this process.

In the disposal of bacon, whatever is shipped for the London market, or any other, both bacon and hams must be packed into a sugar hoghead, or something similar, to hold about ten hundred weight. Bacon can only be cured from the middle of September until the middle of April. (Henderson’s Treatise on Swine, p. 59.)

Sect. V. Diseases of Swine.

Swine are subject to various diseases, but according to Lawrence they are not easily doctored.

They are subject, he says, to pox or measles, blood striking, taggers, quincy, indigestion, catarrh, peripneumonia, and inflammation of the lungs called hogsings. When sick, pigs will eat, and they will take medicine in their wash; when they vomit, they eat, there is no help for them. Hops, ginger, sal volatile, and alteratives, sulphur, antimony, and madder are our grand specifics, and they are truly useful. As cordials and tonics, treacle and strong beer, in warm wash, and good peas and polled. In the measles, sulphur, or new sal volatile, should be given; if they recover not, give them good cordials of cordials now and then; in taggers, bleeding, fresh air, and perhaps nitre; in catarrh, a warm bed, and warm cordial wash; and the same in quincy, or inflammation of the glands in the throat. If external suppuration appear likely, discharge the matter when ripe, and dress with tar and brandy; or hang them up, and dress it with a half round and shirt, and pigs, like the unbounded of the liver in lambs, is sometimes found to be hereditary; there is no remedy. This disease in pigs is often the consequence of colds from wet lodging, or of hasty feeding in a poor state; in a certain stage it is highly inflammatory, and without remedy. Union with train oil, and the internal use of Be, have been sometimes thought beneficial.

Chapter VIII.
The goat, Rabbit, Hare, Dormouse, Deer, and various other Animals, that are or may be subjected to British Agriculture.

The goat (Capra Aegagrus L., fig. 905.) is a native of many mountainous parts of Europe, Africa, Persia, and India: he is domesticated throughout Europe, feeds on branches of shrubs, on lichens, hemlock, &c.; is seldom destitute of horns, of active habits like the deer, treacherous, petulant, roaming, and ascripicious; gravid four months and a half, brings from one to two at a birth, and lives ten or twelve years. The female will allow itself to be sucked by the young of various other animals; and a foal which has lost its mother has been seen thus nourished by a goat, which, in order to facilitate the process, was placed on a barrel. The attachment between the nurse and foal appeared strong and natural: in its internal structure, it ex-
tremely resembles sheep, but is far superior to them in alertness, sentiment, and intelligence. The goat approaches man without difficulty, is won by kindness, and capable of attachment. The extremely unpleasant odour attending these animals is supposed to be beneficial, and horses appear so much refreshed by it, that a goat is, on this account, often kept in the stables of the great. It is a singular local peculiarity, that in Angora only, the animals of the Capra, O'vis, and Lépus tribe, have long soft silky hair.

7382. *The Angora goat*, a native of Turkey, is chiefly valued for its exquisitely fine hair down, which grows under its coarse hair, and of which the Cashmere shawls are manufactured. The down is obtained by gently combing the animal. A considerable number of this breed are imported from Persia and Turkey, and stationed at St. Omer's, with a view to their increase, and the establishment of the shawl manufacture. The kids of this flock are said to be abundantly covered with down and hair, and superior in strength and appearance to indigenous French kids. When the goats of this kind degenerate, when the animals are removed from the pasture of Angora; but this is likely in part to arise from the neglect of cleaning and washing them, which at Angora is to assiduously attended to. By a late Report of M. Termeaux to the Paris Agricultural Society, the French Angoras have increased since the year 1819, as equally with the French kids, as with the goats, and are not taste of. They will feed on grass in pastures; but, as they love browsing on trees much better, great care should be taken to keep them from valuable plantations.

7383. The Angora goat, or as it is called, is, in some respects, a species of the Cashmere shawl goat, and will be afterwards noticed.

7384. *The Chamois goat*, a native of Switzerland, is a species of antelope, and will be afterwards noticed.

7385. *The goats of Wales* are generally white, and are both stronger and larger than those of other hilly countries. Their flesh is much used by the inhabitants, and often dried and salted, and substituted for beef. They are much the kind of goats valued for gloves, and were formerly employed in furniture, when painted with rich colours, of which they are particularly capable, and embellished with artificial flowers, and worked in gold and silver. The goats may be of some advantage in rocky barren countries, where nothing else can get a support for life. They will climb the steepest rocks, and there browse upon briar, heath, and shrubs of various kinds, and eat leaves and flowers without taste of. They will feed on grass in pastures; but, as they love browsing on trees much better, great care should be taken to keep them from valuable plantations.

7386. *The produce of the goat*, from which advantage chiefly obtained, is the milk, which it yields in large quantities, and which is accounted the best milk of all animals. They mix this and cows' milk together in some parts of the kingdom, and a very valuable cheese is made from it. Besides this, the kids or young goats are very fine food, and the best kind of beef or three or four at a time, and that twice a year.

7387. *Goat's hair* is also valuable; it may be sheared as the wool from sheep, and is excellent for making ropes that are to be used in the water, as they will last a great while longer than those made in the common way. A sort of stuff is also made of it in some places, and that of a coarse quality.

7388. The *sweat of the goat* is also in great esteem. As many of the inhabitants of Caernarvonshire kill them merely for the sake of their fat, which makes a candle of superior quality to the common. Of their horns excellent handles are made for tucks and penknives. The skin is peculiarly well adapted for the glove manufacturer, especially that of the kid, as it takes a dye better than any other skin. The old skin is also of great use, being preferred to that of the sheep, and the flesh affords a cheap and plentiful provision in the winter months, particularly when the kids are brought to market. The haunches of the goat are frequently salted and dried, and supply all the uses of bacon: this by the Welsh is called cock yr wden, or hung venison.

7389. The kind of goats for keeping to advantage should be chosen in this manner:—The male should have a large body, his hair should be long, and I could not say how long!; the neck should be plain and short, the head small and slender, the horns large, the eyes prominent, and the beard long. The female should have a large upper size, with large teats, and no horns, or very small ones. Goats should be kept in flocks, that they may not straggle; they should, as well in winter, as in summer, be sheltered both in the open shelter of the pen, and coupled in December. They should have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the same manner as our sheep are.

7390. *The Cashmere shawl goat* has been successfully introduced into England, by C. T. Tower, Esq. of Weald Hall, Essex; and as that gentleman by this time must have some of his flock to dispose of, we think their introduction among cottagers for their wool, and also, as suggested. (Gard. Mag. vol. v. p. 552), for their milk, is a fair subject for some of our female readers to speculate on. This variety of the common goat, or probably it may be a distinct species, is a fine-looking animal, and would be very ornamental in a park, on a ruin, on the roof of a cottage, or in a churchyard. It would also be very pleasant to have a handsome Cashmere shawl. We shall therefore give all the information we can on the subject from Mr. Tower's account, as published in the last volume of the Transactions of the Society of Arts. These goats were brought from Persia to France during the time of Napoleon, and under his patronage, by the celebrated M. Termeaux, in 1821. Mr. Tower, happening at that time to be in Paris, purchased four of them, two males and two females, and conveyed them in a covered vehicle to the park of Weald Hall, where they have been kept ever since, is on foot, and the situation is much exposed. The animals have, nevertheless, continued in health and multiplied rapidly; so that his present flock consists of twenty-seven, including the four original ones. Of these latter a polled female, which was old when purchased by him, has every year produced at least one, and sometimes two twins. Those individuals of which the horns cross are in Persia esteemed the best; and one of Mr. Tower's last year's kids has this peculiarity. They show no impatience of cold, and are very healthy, requiring only the occasional care of an old sheep. In spring and summer, and the goat both in winter and during winter have been fed with hay, and refuse vegetables from the garden; but their favourite food is porse (Pex europa'), which they devour eagerly, without being annoyed by its prickles. They damage young plantations, but not more than the same damage done by goats. They offer greater choice to Mr. Tower's goats this year produced kids before they were themselves a twelvemonth old. A few produce brown wool; but that of far the greater proportion of the goats is white, and this latter is more valuable than the other. The goat is a mixture of long coarse hair, and of short fine wool; this latter begins to be formed early in April, and is collected easier than the former. The wool is three times, with such a comb as is used for horses' manes. A good deal of the long hair comes off at the same time, but the manufacturer has found no difficulty in separating it. The produce of a male is about four ounces, and of a female about two ounces. Two ounces of wool as it comes off the goat's back may be estimated to make one shawl, fifty four inches square. It will therefore require ten goats, male and female, to furnish materials for one shawl. Mr. Tower has this year had three shawls made of his wool.
of Norfolk and Cambridgehire. They sometimes extend to 3000 or 3000 acres, and many have been lithero considered to pay better in that state than in any other. Arthur Young, however, has shown in his Survey of Lincolnshire, that though a rabbit warren may afford a high interest on the capital of the occupier, yet the rent it affords to the owner of the soil is less than would ultimately be obtained by planting or breaking up, and laying down with chicory or some other suitable herbage plant. In the mean time, as they continue to exist, and are subjected to a kind of management, we shall submit a short outline of it under the heads of extent, soil and situation, fencing, stocking, breeding, rearing, and produce. Afterwards we shall take a view of the mode of managing rabbits in hutches.

7343. The extent of warrens varies from 100 to 5000 acres, but a common size is considered to be 1500 or 2000 acres. The land, sandy, warn, and poor; rich grass or herbage being found to produce a scouring, which sometimes carries off the greater part of the stock. Warrens are generally enclosed with walls either of stone or turf, an essential addition to the latter being a coping of flints, slate, or stiff straw. Fishing is used in some places, but a brook is found insufficient, as the rabbits have been found to swim across.

7344. Warrens are often stocked by nature, and all that art has to do in that case is to protect the produce; but in some cases they are formed on ground where rabbits do not exist naturally, or where they exist it is considered desirable to change the species or double the breed.

7345. In stockin a warren, whether the surface be flat or hilly, artificial burrows are sometimes made, to reconcile the rabbits to the ground, and to preserve them from vermin, until they have time to make their own burrows. These are bored with augers, or made by rabbits enough to make a burrow of a sufficient width. In a level warren, these augers may, from time to time, be found useful in forming such holes. They, however, in most cases, are capable of making burrows for themselves. Some warren lands are stocked in the proportion of three couple to an acre; which, however, is considered by others it should be one male rabbit is said to be sufficient for one hundred does, or females; but this is certainly a much larger proportion than in most other districts. On the warrens of Yorkshire, according to Marshall, one male is considered sufficient for only six or seven females, and any larger proportion the greater the stock of young of the age, or more than expected, it being the nature or economy of the males to destroy their young, especially when the proportional number is too great.

7346. The varieties employed as stock for warrens are the common grey and silver grey breeds: the former of which is found to be considerably more hardy and much better for the purposes of food, but the latter has greatly the advantage in the value of the skin. Till lately, the common grey rabbit, probably the native wild rabbit of the island, was the only species. At present, the silver-haired rabbit is got after, and has, within the last few years, been introduced into most warrens. The skin of the grey rabbit is cut; that is, the wool is pared off the pelt, as a material for hats; whereas, that of the silver-haired rabbit is dressed as fur; which, it is said, goes principally to the East Indies. The colour is a black ground, thickly interspersed with single white hairs. The skins of the grey variety sell for a dozen more than those of the common sort; a sufficient inducement for propagating it in preference to the grey breed.

7347. The rabbit begins to breed at an early age, as at eight, ten, or twelve months, going only about two weeks from her birth than three weeks after they appeare from the burrows, during which time they are suckled twice in the day by the mother. It is, therefore, evident, that they may breed seven times in the course of the year under good keep, as the does take the buck almost immediately after producing their young. In warrens that are enclosed it is, however, said that they can breed seven times in two or three times in the year.

7348. The management of a rabbit warren is a very simple business. Birds and beasts of prey are to be kept off by taking them in traps; dogs and cats kept off, and rats, moles, mice, and other vermin destroyed in hedges or troublesome. Man himself, if he be guarded against in some situations. Additional food is to be supplied in the winter season, when the weather is severe, such as green hay, salt, tallow, clover, turnips, and others of the same sort, which must be distributed over the warrens. It is supposed that an additional food is given to the rabbits in those parts of the warren, which, by some reason or other, are not occupied by the hares. It is, therefore, evident, that it is necessary to clear it away from the ditches or fences to prevent the rabbits from getting over them.

7349. This sort of stock is mostly taken by nets or traps, set in the form of a fold between the places where they run and those where they feed. The rabbits being hunted into them as they return from feeding. Sometimes they are taken by ferrets and terriers. The fold warrens, Marshals says, have three ways of catching their rabbits; with fold nets, with spring nets, and with traps, a species of trap. The fold nets are set about midnight, between the burrows and the feeding grounds, the rabbits being driven in by dogs, and kept enclosed in the fold until morning. But the spring nets are not so well used as the traps, generally laid round a haystack or other place where rabbits collect in numbers. It is added, that the trap is a modern invention. It consists of a half or outer screen, formed within the ground and covered with a floor, and with one large trap-door, towards which the rabbits are led by a narrow groove. This trap, on its first introduction, was set mostly by a haystack, hay being at that time the chief winter food of rabbits, or on the outer side of the warren wall, where rabbits were observed to scratch much, in order to make their escape. Since the cultivation of turnips and good hay for this species of animal, the trap has become a part of the general stock for rabbits. When it is once set, it is closed and the rabbits are caught in an enclosure within the warren, a trap is placed within the wall of this enclosure. For a night or two the mouth is left open and the trap kept covered (with a board or triangular rail), in order to give the rabbits leisure to retire. Whenever the rabbits learn to retreat, the trap is shut tight. Then a second trap is set within the first, and the same is repeated. Thus the warren is gradually closed, and the rabbits confined in a small space, when they are taken.
system of management. The produce is the largest on new lands; however, much of the profit must always depend on situation, so as to be near good markets. These animals are in what is termed season from the end of October to the beginning of January, in which period the best skins are produced: of course a large proportion of the best skins of the season. The produce is so fine that the skin is killed in this season, the tail, head, and feet by the purchasers are called half skins, quarter skins, and racks, sixteen of which are only considered as a whole skin. The rabbits are disposed of by the hundred, six score couple being considered as an hundred.

7.31. The breeding and rearing of tame rabbits is carried on in hutches or stores of boxes placed in sheds or apartments of any kind secure from vermin. We shall give a view of the practice as to rabbitry and furniture, varieties, breeding, feeding, and produce.

7.32. The rabbit-house should be particularly dry and well ventilated, as these quadrupeds are very subject to the rot and to liver complaints like sheep.

7.33. The huts or hutches (Fig. 983, 985) are boxes or chests, eighteen inches or more high, and from two and a half to three feet wide, placed in groups of five to six, thus forming a single row, and thus communicating by sliding doors, the use of which is to confine the rabbits in the inner division (a), whilst the outer, which has a wire door (Fig. 989), is cleaning. Generally these hutches are placed in rows about each other against one side of the rabbit-house, and sometimes they are placed in the open air, against a wall, with a wired or netted enclosure. Sometimes they are ranged along the floor, but the nearest mode is to place them on brackets round the room, or on stands about three feet high on the floor. In both these cases it is to be understood that they are not allowed to run about the rabbit-room, the use of which is solely to enclose and protect them in an atmosphere of moderate temperature, and to contain a bin with bedding of clover hay, and any such food as they may eat and thrive upon. The utensil for feeding rabbits so hutchled is simply a trough (e), which may be formed of pewter, very hard wood, earthenware, or cast iron, as rabbits are very apt to gnaw them; and it should be divided on the surface crossways every four or six inches, to prevent them from scratching and throwing out their corn. Some add a small rack for their clover, but that will not be lost if given on the floor in small quantities.

7.34. The rabbits of the Angora breed yield in Normandy a wool which serves as a primary material in several of the most fashionable manufactures, and is used above all for the hosiery trade. The rabbits are found to delight more than anything in the leaves of the Robinia pseudacacia; and as this plant grows on common sandy soils, it has been proposed to cultivate it for the sake of these rabbits.

(Com. to Board of Ag., vol. i. p. 299, 300.)

983. There are numerous varieties of tame rabbits; but the broad-chested and short-legged are the most hardy, and fatten most expeditiously. There is a large variety of the hare colour, which has highly-coloured and high-flavoured flesh, more savoury than that of the common rabbit; they make a good dish cooked like the hare, which at about eight months old is nearly equal in size, and which has a white and yellow and white species have whiter and more delicate flesh, and cooked in the same way will rival the turkey. The Turkish or French rabbit is esteemed by some, but differs little from the common variety. All these and other varieties are to be had from the London dealers and poultrymen.

The doe will breed at the age of six months, and the period of gestation is thirty or thirty-one days. It should be premised, that the buck and doe are by no means to be kept together; but their union having been successful, the buck must be immediately withdrawn, and the doe tried again in about three days; in fact, with rabbits this business is conducted on the same principle as in the stud. Like chickens, the best breeding rabbits are those kindled in March. Some days before parturition or kindling, hay is to be given to the doe, to assist in making her bed with the flue which nature has instructed her from her body for that purpose. She will be at this period seen sitting upon her haunches and tearing off the flue, and the hay being presented to her, she will with her teeth reduce and shatter it to her purpose. Bitting down of the litter or bed is the first sign of pregnancy. The number produced, generally between five and ten; and it is most advantageous always to destroy the weak or sickly ones as soon as they are perceived; because five healthy young, a dozen to a hundred, and generally two hundred, is the number of an opposite description, and the doe will be far less exhausted. She will admit the buck again with profit at the end of six weeks, when the young may be separated from her and weaned: or the young may be suckled two months, the doe taken back at the end of five weeks, so that the former litter will have been about a week before the next parturition; and it is best for giving the buck immediately after the doe had brought forth, lest she should pine, and that no time should be lost; and if it were intended that no time might be lost in destroying the doe, such indeed would be the most successful method. The Great care should be taken not to approach the buck, or indeed by any other rabbit; as, from being harassed about, she will almost certainly cast her young. One doe in a thousand may devour her young; the sign that she ought to be otherwise disposed of. Some does admit the buck with difficulty, although often apparently in season; such should be immediately fattened off; since it can never be worth while to keep any individual for breeding of a stock to be produced in such multitudes against which there lies an objection. Should the doe lie weak on her bringing forth, from cold, cough, or other causes, she will drink beer, caudle as well as any other. She may be covered with fresh grain, which will comfort her, and which may be mixed a small quantity of cordial horse balm. With due attention to keeping them warm and comfortable, and guarding against every sudden impression from cold, and more particularly moist and wet. If the young are not more being fed, rabbits may be bred throughout the winter, with nearly equal success as in the summer season; but in both cases the produce is so so fine and so small, that one might well be satisfied with four or five litters during the best part of the year, giving the doe a winter feller.

7.35. Feeding. According to Mowbray, it is better to feed three times than twice a day. The art of feeding rabbits with safety and advantage is, always to give the upper hand to dry and substantial food. Their nature is congenial with that of sheep, and the same kind of food, with little variation, agrees with both. However, the refuse of goose or beef, and all such food as vegetation should be very dry and encrusted, and can never be worth while and exertions of the field may be obtained in such plenty, and will return so much greater profit. Rabbits may be kept, and even fattened, upon roots, good green meat, and hay; but they will pay for corn, and this may be taken as a general rule. The grass rabbits which have the least to be said for the harm from being indulged with almost an equal portion of good substantial vegetables. However, the test of health is that their dung be not too moist. Many or most of the town feeders never allow any greets at all, because, instead of this they feed all manner of coarse grains. The common feed for rabbits is oats, peas, wheat, pollard, and some give buck wheat: the greens and roots the same as our cattle crops; namely, carrots, Jerusalem artichokes, if potatoes, baked or steamed; lucerne, cabbage leaves, clover, &c. Mowbray has had the hoven from cattled beasts of a more fibrous kind have a similar effect. The best dried herbage is clover and meadow hay, and pea and bean meal.
greater weight, better quality, and more profit, which is generally the case in the feeding of all animals. Some fatten with grains and pollard. Mowbray tried wheat and potato oats comparatively, but could find no difference in the goodness of their flesh. The rabbit's flesh being dry, the allowance of succulent greens may tend to render it more juicy; and probably the old complaint of the dryness of the flesh in Devon hares, entirely fed with hay, might be remedied in the same way. Rabbits are in perfection for feeding at the fourth or sixth month; beyond which period their flesh becomes more dry and somewhat hard. It requires three months, or nearly so, to make a rabbit thoroughly fat and ripe; half the time will make them eatable, but by no means equal in the quality of the flesh: they may yet be over fattened, as appears by specimens exhibited a few years since at Lord Somerville's show, which were loaded with fat, without and within, like the best feeding sheep.

The flesh of the rabbit is esteemed equally digestible as that of fowls, and equally proper for the table of the invalid.

Castrated rabbits might be fattened, no doubt, to the weight of upwards of ten pounds, at six or seven months old. It is said to be successfully practiced in Sussex, near Chichester, where on the average not one in three hundred is lost by the operation, which is performed at five or six weeks old. With respect to the quantity of corn consumed in fattening, a young buck which weighed three pounds, fit for the spit, was put up in good case in August, and was only one month in feeding, consuming not quite four quarters of oats, with hay, cabbage, lucerne, and chicory; the skin, silver and black, worth fourpence.

In slaughtering full-grown rabbits, after the usual stroke upon the neck, the throat should be perforated upwards towards the jaws with a small pointed knife, in order that the blood may be evacuated, which would otherwise settle in the head and neck. It is an abomination to kill poultry by the slow and torturing method of bleeding to death, hanging up by the heels, the veins of the mouth being cut; but still more so the rabbit, which in that situation utters horrible screams. The entrails of the rabbit, whilst fresh, are said to be good food for fish, being thrown into ponds.

The rabbit is a caressing animal, and equally fond with the cat of the head being stroked; at the same time it is not destitute of courage. A whimsical lady admitted a buck rabbit into her house, when he became her companion for upwards of a twelvemonth. He soon intimidated the largest cats so much, by chasing them round the room and darting upon them, and even leaping over their heads, tails, and ears, that they very seldom dared to approach. He slept in the lap by choice, or upon a chair or the hearth's rug, and was as full of mischief and tricks as a monkey. He destroyed all the rush-bottomed chairs within his reach, and would refuse nothing to eat or drink which was eaten or drank by any other member of the family.

Diseases. No live stock is less liable to disease than the rabbit, with regular and careful attention, as has been pointed out; so that any sudden and accidental disorder is best and most cheaply remedied by a stroke behind the ears. But want of care must be remedied, at all, by an opposite line of conduct. Thus, if rabbits become pot-bellied, in the common phrase, from being fed on loose vegetable trash, they must be cured by good hard hay and corn, ground malt or peas, or any substantial or absorbent food. Their common liver complaints are incurable, and when such are known, the best that can be done is to be observed. They will not bear to be pushed beyond a moderate degree of fattness, and should be taken in time, as they are liable to drop off suddenly. The dropsy and rot must not be prevented, as they are generally incurable; nor is a rabbit worth the time and pains of a probable cure.

The hare (Lepus timidus L., fig. 910.), if taken young, may be tamed and domesticated, and has occasionally been nursed by a cat. Somnini the naturalist, and Cowper the poet, had hares in a complete state of domestication. It is the fur of this animal is of greater value for hat-making than that of the rabbit, it would be a very desirable circumstance if it could be substituted for that animal in warrens. Its flesh would certainly be deemed preferable, and in general it is a large animal. It lives on the same sort of food as the rabbit, produces generally three young ones at a time, and breeds at least three times in a year. It is not improbable that in some situations, where the soil is dry and poor, a hare warren or pack might be found to answer; the price in the metropolis being never less than ten times that of rabbits.

There is a hare warren near Banstead Downs: it contains about three acres of ground: 200 brace are usually kept in it; they are fed in the summer on clover, rape, &c.; and in the winter, on hay. The warren is surrounded by a brick wall about ten feet high, with openings at regular distances, within which are wire gratings on hedges: these give way to the hares, when they enter the warren; and they are so constructed, that they immediately close after them, and so prevent their escape.

The Guinea pig, or restless Cavy (Cavia Cobaya L., fig. 911.), is a native of Brazil, but domesticated in Europe, and treated and used like the tame rabbit. In Italy, the flesh is considered a delicacy, and the skins are nearly as valuable as those of rabbits.

The Guinea pig is one of the most profitable of animals, and Buffon calculates that in twelve months only 100 might be produced from a single pair, as it has been known to bring forth young when two months old only; the time of gestation is only three weeks; and she will produce at least every two months. The young are six or seven months before they arrive at their maturity of growth, but within the short period of twelve weeks from their birth are nearly as alert and active as those fully grown, and therefore require parental assiduity only for a little time. Vegetables form their food, and on a great variety of these they will flourish and fatten. They drink but little, appear after eating to ratinate, and are extremely apt to be upset by colds. They are uncommonly clean in their habits, and are often to be seen smoothing and cleansing their fur with particular attention and perseverance.

The fat dormouse (Myoxus Glis L.) is a native of the woods of Germany and Russia; and has a good deal of the habits of the squirrel. It feeds on fruits, lays up a winter store, forms its nest in hollow trees, sleeps by day, and grows very fat in autumn.
It was cultivated by the Romans, and highly prized by them as food. The body is six inches long.

7369. (Of the deer (Cervus L.) there are three species in cultivation in this country: the stag, roe, and fallow deer. The latter are now almost exclusively cultivated in parks, as articles of luxury, and, it is conceived, might answer to a small extent in farming.

7370. The stag (C. Elaphus L., fig. 912. a) is found in nearly all the temperate climates of Europe and Asia. It is also found in North America, but attains its largest size in Siberia. From the branchiness of its antlers, the elegance of its form and movements, and the strength of its horns, it attracts particular admiration, and may be regarded as a principal embellishment of the forest. The stag is remarkable for a fine eye, and an acute sense of smelling. His ear also is exquisitely sensitive, and musical sounds appear to possess over him the power of exciting complacency, if not rapture. His enemies not unfrequently employ the shepherd's pipe to decoy him to his destruction; and Playford, in his Introduction to Music, states that he once met a herd of twenty stags near Royston, which readily followed the tones of a violin and bagpipe, played by their conductors, but stopped whenever the music was suspended. Their whole progress from Yorkshire to Hampton Court was attended, and it was supposed extremely facilitated, by these sounds. The stag is simple and unsuspicious, and employs no arts to avoid detection or pursuit, until after having received considerable molestation. His food consists in winter of moss and bark; in spring, of the catkins of willow and hazel, and the flowers and buds of cornel; in summer, of the grain of rye, and the tender shoots of the alder; in autumn, of the leaves of brambles, and the flowers of heath and broom. He eats with slowness, and ruminates with some considerable effort, in consequence of the distance between the first stomach and the mouth. In March, generally, he sheds his antlers, which are not completely renewed till August. He will live to between thirty and forty years of age, and was formerly, amidst the other vulgar errors of antiquity, supposed capable of attaining most extraordinary duration. The stag is supposed to have been introduced from France into England, where he has latterly been made to give way to the fallow deer, an animal more gentle in its manners, and more valuable as food. In some parts of Scotland he is yet to be found in his original wild state. A stag of five years old is, in hunting, termed a hart; the female, hind; and the young, fawns.

7371. The roe (C. Capreolus L., fig. 912. b) is the smallest of the deer tribes which are natives of Europe; it is generally of a reddish brown colour, graceful, sprightly, and courageous, particularly cleanly, and delighting in dry and mountainous situations: it leaves a strong scent behind it, but possesses such arts of defence, that by various doublings and intermixtures of past with present emanations from its body it frequently baffles the most experienced dogs, and remains in a state of security, while the full pack passes almost close by its retreat, distinguishing it neither by sight nor smell. It differs from the stag in the constancy of its attachment, and the parents and their young constitute a family, never associating with strangers: two fawns are generally produced by the female at a birth, one of each sex, which, living together, form a mutual and inviolable attachment. When one of a new family is to be nursed, the female is driven off to provide for itself, but returns again after a certain interval to the mother, whose former affection is restored: a final separation speedily takes place, however, soon after this return, between the fawns of the season preceding the last and their dam; and the former remove to a distance, constituting a distinct establishment, and rearing an offspring of their own. When the female is about to bring forth, she secludes herself in some remote recess of the forest, from which she returns at the end of about ten days with her fawns, just able slowly and weakly to follow her steps: in cases of danger she hides them in a place deemed by her most secure from the enemy, and attracts the attention of the latter from them to herself; happy, by her own perils or even destruction, to effect the security of her offspring. In winter, these animals feed on brambles, broom, heath, and catkins; and in spring they eat the young wood and leaves of almost every species of tree, and are said to be so affected, as it were with intoxication, by the fermentation of this food in their stomachs, that they will approach men and other enemies: when they generally shun with great care without apprehension or suspicion. The flesh of these animals is excellent, though after two years of age that of the males is ill-flavoured and tough. The roe exists now in no part of Ireland, and, in Great Britain, only in a few districts of the Highlands.

7372. The fallow deer (C. Dama L., fig. 912. c) is in general much smaller than the stag; but in Spain is nearly equally large. In France and Germany it is rarely to be found, and it has never been known to have existed in America. It has the elegance of the stag, connected with a much more tractable disposition. It sheds its antlers, which, as in the stag species, are peculiar to the male, every year; is stated to live to the age of twenty years, and arrives at its maturity in three; it is by no means fastidious in its food.

7373. Deer husbandry. The author of the Agricultural Survey of the County of Westford observes, that, "the Earl of Clarendon, justly considering that there is no more improperity in converting one animal to profit than another, makes deer an object of husbandry. As soon as the rutting season is over, or usually about the 10th of November, his lordship selects from the herd the weak ones, some of which would probably die in the winter, and keeps them in a small yard that has a shed on one side, and a net over the whole against pigeons, &c.; the spot very warm, and well sheltered. Their antlers are immediately sawn off, the skin is well dried, and they are fed a small expense on pea-straw, hay, &c. warmth making up for the want of better food. At times, during the winter, they have clover, hay cut into chaff, and if they do not eat it well, a little salt is added. They have always plenty of water, and are
kept perfectly clean: much attention should, he says, be paid by the keeper to make himself familiar with them, that he may enter the place without disturbing them. The finest week in March he gives them oil-cake, about half a cake each a day, with chaff, which fattens them so quickly that all are done by the end of March. Before killing they have some green meat given, to take away any ill flavour from the cake, supposing such to be the effect of the food; for it is certain that the venison is exceedingly good. As to weight, a hunch usually weighs about 44 pounds; a brace is sold for 15 guineas. The antelope, woods and near the keeper's perquisite; so that the value of a brace amounts to 17s. 17s. exclusive of some trifling articles. The purchaser sends for them. It is added, that his lordship usually fattens nine brace: his whole winter stock rises to 250 head, in a park of 250 acres, but much of it is quickly covered with timber; thirty sheep and ten cows also feed on it. The park consumption of hay amounts to thirty-two loads, being reduced to that quantity by the use of much browse; all ash, elm, and Scotch pine being brought for that purpose before bagging, which not only saves hay, but improves the flavour of the venison.

One of the most dangerous, it affords the means of having good venison until Christmas, without any other sort of food than the common grass; they also fatten more quickly; the operation must, however, be performed while they are quite young.

(Devonshire Report.)

7375. The moose deer, or elk (Cérvus Alces L.), is indigenous in Europe, America, and Asia, as far as Japan, and was formerly wild in this country, though now extinct. It is of the size of a horse; gentle, except when teased by the gad-fly; feeds on twigs and branches of trees, and marsh plants; goes on its hoofs with a shambling gait at the rate of fifty miles a day; has a skin so hard as almost to resist a musket ball, but flesh tender and good. This animal might be introduced as an inhabitant of parks, where it would add to the variety of animated woody scenery and of venison.

7376. The rein deer (Cérvus Tarandus L., fig. 913) is an inhabitant of the alpine mountains of America, Europe, and Asia, and is too remarkable an animal, and too well known, to require a particular description or account of his habits.

7377. The tame variety have been introduced more than once into this country by the Hon. Daines Barrington, Bullock and others, but cannot be kept in parks on account of the want of their particular lichen. As this lichen abounds on several mountains in Yorkshire, and on many in Scotland and Ireland, some patriotic and curious noblemen might attempt its cultivation. The milk and cream, as Dr. Clarke states, are most excellent, and also the flesh; and even this article of profit, the sale of the animals as breeding stock would pay for a time. Lichen hay might no doubt be imported at an easy rate from the gulf of Bothnia; and the animal by degrees in the course of a few generations might be habituated to grass or the spray of trees.

7378. The antelope (Antelope L.) is a beautiful and numerous genus of animals, partaking of the nature of the goat and deer. Two species, the A. Saliga, or scythian, and the A. Rupicapra or chamois, are natives of Europe, but the rest of hot climates.

Antelopes, Pennant observes, are animals generally of a most elegant and active make, of a restless and timid disposition, extremely watchful, of great vivacity, remarkably swift and agile, and most of their bounding so light and elastic as to strike the spectator with astonishment. What is very singular, they will stop in the midst of their course, gaze for a moment at their pursuers, and then resume their flight. As the chase of these animals is a favourite amusement with the Eastern nations, that can be collected proofs of their rapid speed. One of the highest compliments that can be paid to female beauty in the Eastern regions is, Atte et Cazet, 'You have the eyes of an antelope.' Some species of antelopes form herds of two or three thousand, while others keep in troops of five or six. They generally reside in hilly countries, though some inhabit plains; they often browse like the goat, and feed on the tender shoots of trees, which gives their flesh an excellent flavour.

7380. The common antelope (A. Cervicapra L.) abounds in Barbarry, and in all the northern parts of Africa. It is somewhat less than the fallow deer: its horns are about sixteen inches long, and lie with prominence to the top, where they are twelve inches distant from point to point. The horns are remarkable for a beautiful double flexion, which gives them the appearance of the lyre of the ancients. The colour of the hair on the back is brown, mixed with red; the belly and inside of the thighs white; and the tail short.

7381. The chamois antelope (A. Rupicapra, fig. 914 a) was formerly considered as belonging to the genus Capra, and is generally called the chamois goat. It is found on the mountains of Switzerland, where it is very shy, and hunted both for its flesh and skin. 394.

7382. The Scythian antelope (A. Saiga L.) bears a good deal of resemblance to the common goat, and it is fully as easily tamed. They are found in immense flocks on the banks of Borysthenes and other parts of Russia, where they are valued both for the flesh and their skin, which is equal to that of the chamois for gloves.

7383. The nilgai, or white-footed antelope (A. picta L., fig. 914 b), is a large and beautiful species, known only within the space of a few years past. Its height is four feet one inch to the top of the shoulders; its length, from the bottom of the neck to the base of the tail, four feet; and the colour a fine dark grey. The nilgau has of late years been often imported into England, and has bred in England. In confinement, it is generally pretty gentle, but is sometimes seized by fits of sudden caprice, when it will attack with great violence the object of its displeasure. The nilgai is said to go
with young about nine months, and to produce sometimes two at a birth: the young is of the colour of a fawn.

7384. The above and various other species of antelopes might probably be acclimated and introduced in parks as objects of luxury. The cultivator who first succeeded in breeding them would find an ample demand at his own price if they happened to come in vogue.

7385. The camel (Camelus L.) is a genus of which there are several species, three of which, the dromedary, or Arabian camel (fig. 915), the Bactrian camel, and the lama or Peruvian sheep, might certainly be partially acclimated in England, as the first is in Italy. (297.) They live upon a very little of the coarsest herbage; might have a warm house well littered to retire to in winter, or in cold nights, and would form a singular ornament to park scenery. Besides their hair and skin are valuable, and they might be sold perhaps to romantic travellers or cavalier quacks.

7386. The lama (Camelus Glama L., fig. 916.) is the camel of South America; and appears to hold a middle place between the sheep, deer, and camel.

7387. Before the entrance of the Spaniards, llamas were the only beasts of burden known to the South Americans. Like camels, they travel slowly, but are persevering, tractable, and very sure-footed. Since the introduction of mules, they are much less cultivated; but before they were depended on to carry the ores dug out of the rich mines of Potosi. The lama is furnished as the camel with ability to abstain from water, by keeping a quantity in its second stomach. Like the camel, its feet also divide, and spread out by no means equal to those of the camel. It is also furnished with a singular protruberance or spur behind, which enables it the better to hold on the ground. The tame are of various colours, and some of them are smooth and others rough. The height of the llama is about four feet, and its length from the neck to the tail about six feet. It has a capacity of throwing out the saliva to a considerable distance, but which is not possessed of any acid quality.

7388. The camelopard (Camelopardalis Giraffa L.), a most singular and noble animal, seventeen feet high, and as tame and gentle as the camel, might also be naturalised. It lives on the green spray of trees and grass, and frequents forests.

7389. The elephant, rhinoceros, musk ox, and a variety of other exotic domestics, might be so far acclimated as to live in Britain as they do in the Jardin des Plantes at Paris, viz., with an enclosure for each sort, and a lodge or house for protection in winter or during inclement weather. Were as much attention paid to acclimating foreign animals as there is directed to the same branch of culture in plants, we should soon possess a rich Fauna; and the public taste may in time take this direction.

7390. In acclimating the more tender animals, it might be desirable to rear a few generations, first in the south of Italy or in Spain, next in France, and afterwards in the south of England. But the camel, musk ox, zebra, quagga, and antelope might be had at once from the acclimated stock in Italy.

7391. The dog (Canis familialis) is an animal of universal utility and interest. From the earliest ages he has been the companion and assistant of the herdsman; and without his aid the flocks must have been confined to narrow limits, and consequently their propagation would have been greatly lessened. But hardy and bold, he watched by night, and toiled by day; securing his charge from the human thief, or the ravenous predatory beasts in the one, and collecting and organising their march during the other. Without the dog, sheep-farmers of the present day would be often at a loss to restrain the wanderings of their flocks; nor is he less useful in guarding the yard by nightly watchings.

7392. The genus Canis includes other animals, as the wolf, the fox, the jackal, and the hyena; and many naturalists have supposed our subject, the dog, to be only a mixed animal, originating from the union of some of these. Such is the opinion of Gmelin, Schinz, Pallas, and Pennant; while the higher names of Blumenbach and Cuvier are ranged among those who assign him a distinct and specific origin. Blaine, who has long successfully advocated the cause of the dog, has bestowed much research on this point; and appears clearly to have traced the dog through his numerous varieties, to a specific origin, but whether originating from a specific or a spurious source, the dog has descended down into such immeasurable varieties, that a detail of the forms and properties of them, as they appear among us only, would be utterly impossible. The wants as well as the luxuries of man have, however, laid hold on some of these varieties, and have fixed them into permanencies, by confining the sexual intercourse to their congeners alone; and of this number there are no less than forty. It would be unnecessary to draw the character of the dog as stated at length by Linnæus and others; the outlines are the same in all.
7393. The shepherd's dog, in an agricultural point of view, ranks foremost among the numerous varieties of dogs which possess the most of the whole race of dogs. But did no other diversity of character, an insuperable one would be found in the opposite characters which different breeds of the same species and different individuals. Few animals can be more unlike than the small sheep-dog of the Highlands of Scotland and dog possesses.

7394. The English sheep-dog is usually larger than the northern, is longer on the legs, and has been so long accustomed to have the tail taken off nearly close to the rump, that he is all standoffish and peculiarly liable to have the pointed end serrated. The shepherd's dog is not, however, usually bred so large as the Highland sheep-dog nor as the real cattle or dog-rider's but is yet sufficiently strong and fierce. The Highland sheep-dogs, the common shepherds of the Highlands, are of a most interesting character. Some of them are smooth-coated; but by far the greater number are rough, and have their hair crisp and, which enables them the better to bear the effects of continued exposure to wind and weather. The bred taller, and either smooth or rough, according to the circumstances. The very term cur destroys all individuality of character; it being applied to characterize any dog of spurious origin: neither in England nor Scotland is there a characteristic difference whatever observed in forms, qualities, or uses. When the sheep-dog is generally employed in watching the farm-yard, he becomes the more fierce and active; he accommodates his powers to the particular circumstances required of him; he knows every field, and every beast, and keeps the whole in subjection. His bite is keen, and principally directed at the heels of cattle, by which he makes himself safe, and does not injure them.

7395. The sheep-dogs of Scotland are varied in form, and size, and colour, and are, all of them usually smaller than those in usual in England; they are, nevertheless, without competitors in sagacity and quickness. Their general characteristics are, ears partially upright, head and eyes, and coat in keeping with the breed. In driving a number of sheep to any distance, a well trained dog never fails to confine them to the road: he watches every avenue that leads from it, where he keeps them, threating every delinquent; and pursues the stragglers, forcing them back to the ranks without doing them any injury. If the herdsman be at any time absent, he rests satisfied, knowing his dog will not abandon his charge, but will keep them together, and the moment he returns, the sagacious animal gives up its trust, or conducts them to his master, according to the word or signal given.

7396. The mastiff or guard (fig. 920) is a noble animal, derived from the Dune, but by selection and cultivation is rendered thicker, more powerful, heavier, though less tall than his original type. The powers of this dog are immense; and as a guard he is indispensable. He has the disposition and character of a sheep-dog, having the ferocity of a tiger to a stranger, with the gentleness of a lamb towards those he knows. His sagacity, his sagacity, the spirit of his actions, his activity, the speed of his feet, the swiftness of his progress, and his liking for being in the midst of all the excitement and all the excitement and all the excitement of the sheep-dog and the sheep-dog, as he is too often used in the disgraceful and inhuman sport of bull-baiting; and however we may admire his inexpressible fortitude, and his attachment to his master, and his master, and his master, and his master, we must admire his inexpressible fortitude, and his attachment to his master, and his master, and his master, and his master.

7397. The pointer, setter, and spaniel dog may not be otherwise considered as connected with the English breed, than as he is too often used in the disgraceful and inhuman sport of bull-baiting; and however we may admire his inexpressible fortitude, and his attachment to his master, and his master, and his master, we must admire his inexpressible fortitude, and his attachment to his master, and his master, and his master.

7398. The terrier (fig. 921) is a dog of very great utility, and of very varied form and size. His qualities are gained him the greatest care in selection, training, and continuing the numerous distinct breeds we have in England, and are of much value in their different peculiarities. The terrier is an excellent guard. The smooth breed produces an endless varieties; the rough breed one of mixed colours, smoother, thicker, and longer; and is used for earing foxes, badger-baiting, and vermin killing in general. It is also of mixed colours, smoother, thicker, and longer; and is used for earing foxes, badger-baiting, and vermin killing in general. It is also of mixed colours, smoother, thicker, and longer; and is used for earing foxes, badger-baiting, and vermin killing in general. It is also of mixed colours, smoother, thicker, and longer; and is used for earing foxes, badger-baiting, and vermin killing in general. It is also of mixed colours, smoother, thicker, and longer; and is used for earing foxes, badger-baiting, and vermin killing in general.

7399. For hunting rabbit, a wry-legged, thick-breasted, is in considerable request. Although the particular varieties are often appropriated to particular purposes, yet all have a common property which renders them invaluable to the agriculturist; which is their Sagacity, keenness of grip, and quickness. To attack the former, they are bred strong, and have in proportion to the size of the bull breed in them; for the latter, their hardiness, activity, and keenness of grip are particularly studied, in which the middle-sized breed is frequently found to excel.
ing the periods between this and the next autumn they may be steadied and practised in fetching their game, etc., as directed in good sporting works. At the commencement of the following season, if they have been well attended to, although only fifteen months old, the whole may be sold to the London or country dealers, to average six or seven guineas each: or if sold privately, they will fetch from eight to twelve and fifteen guineas each, out of which, perhaps, not more than half a guinea can fairly be deducted for keep, &c. The trouble occasioned to the master will be trifling, because connected with a pleasing employ to him as a sportsman, and who will thus have his own sportsmen for nothing.

7401. *Sellers,* as more valuable, will fetch a higher price; but they do not always command so ready a sale, and are more troublesome to break.

7402. *Spaniels* are commonly thought, but most erroneously, almost to break themselves. A really well broken spaniel, however, is so rare, that instead of being worth two or three guineas, which is the usual price, it will fetch from five to ten pounds. It would be even less difficult to the farmer to rear spaniels than pointers, and by following him continually about the grounds they might closely observe the evidence, and close readings, which are the grand requisites, without trouble or expense. In this way, four or five brace might be easily brought every sea-on to market, and would always command a ready sale, and a price according to the perfection of their breaking.

7403. *In the breeding and rearing of dogs for the above purposes,* it is necessary to observe the greatest care in their original selection; that the breed be of the very best, and one which as it were breaks itself, for this shows the purity of the breed. It is likewise no less necessary that the breed be carefully preserved so, to do which, the moment the dogs begin to smell at a bitch, shut her and the intendment closely up, in a confinement inaccessible to other dogs, and there let them remain a fortnight. It is likewise almost equally necessary, that the dogs peculiarly appropriated to agriculturists, particularly the shepherd's dog, should be kept pure; for any animal is more liable to be infected by disease, as it can on any account be permitted; but choice may be made among families of the same variety. In the rearing of this dog, his education should be early and carefully attended to, to make him hardy and familiar with all the signs of the shepherd, who ought himself to be equal to the regular education of his own dog.

7404. *The diseases of dogs are very numerous.* The following are described by Blaine as the most prevalent, with their methods of cure.

7405. *The canine asthma* is hardly ever observed to attack any but either old dogs, or those who, by confinement, too full living, and want of exercise, may be supposed to have become diseased by these deviations from a state of nature. It is hardly possible to keep a dog very fat for any great length of time, without bringing it on. This cough is frequently confounded with the cough that precedes and accompaniments a distemper; but it may be readily distinguished from this by an attention to circumstances, as the age of the animal, its not affecting the general health, nor producing immediate emaciation, and its less readily giving way to medicine.

7406. *Cancer* is often very difficult, because the disease has in general been long neglected before it is sufficiently noticed by the owners. As it is usually brought on by confinement, too much warmth, and over-feeding; so it is evident the cure must be begun by a steady persevering alteration in these particulars. The medicines most useful are alternatives, and of these occasional emetics are the best. One grain of tartar emetic, and two or three grains of calomel, is a very useful and valuable emetic. This dose is sufficient for a small dog, and may be repeated twice a week with great success, always with palliation.

7407. *The disease of the eyes,* dogs are subject to almost as great a variety as ourselves, many of which end in blindness. No treatment yet discovered will remove or prevent this complaint.

7408. *Sore eyes,* though not in general ending in blindness, is very common among dogs. It is an affection of the cilia, and is not unlike the scrofulous affection of the human eyelids, and is equally benefited by the same treatment: an unguent made of equal parts of nitrate of silver and mercury, prepared very hard, and very lightly applied. Dropsy of the eyeball is likewise sometimes met with, but is incurable.

7409. *Cancer* of the virulent dracillal ulcer, that is so fatal in the human subject and is called cancer, is unknown in dogs; yet there is very commonly a large scrofulous swelling of the teats in hitches, and of the testicles, though less frequent; in dogs, that as it sometimes becomes ulcerated, so it may be characterised by this name. In the early state of the disease dresses prove useful, as vinegar with salt, and camphor and Spanish flies, with mercury ointment, have sometimes succeeded; taking care to avoid irritating the part so much as to produce blister. But when the swelling is detached from the vesicle, and hangs pendulous in the skin, it had better be removed, and as a future preventive suffer the bitch to breed. Scrofulous testicles are likewise sometimes met with; for these no treatment yet discovered success out the removal of the part, and that before the spermatic chord becomes much affected, or it will be useless.

7410. *Colic.* Dogs are subject to two kinds of colic; one arising from constipation of the bowels, the other is of a kind peculiar to dogs, apparently portaking of the nature of rheumatism, and also of spasm. From a sudden or violent exposure to cold, dogs become sometimes suddenly paralytic, particularly in the hinder parts; having great tenderness and pain, and every appearance of lumbago. In every instance of this kind, there is considerable affection of the bowels, generally constiveness, always great pain. A warm bath, and the administration of stimulants, but none particularly active aresons to the colic. Colic arising from constiveness is not in general very acutely cured from the pain it produces, sometimes, however, it appears accompanied with more spasm than is immediately dependent on the confinement of the bowels. In the former give active aperients, as calomel with pil. e. caudis, and e. astringent and glister, and in the latter castor oil with laudanum and ether.

7411. *Distemper.* This is by far the most common and most fatal among the diseases of dogs; hardly any young dog escaping it; and of the few who do escape it in their youth, three fourths are attacked with it at some period afterwards; it being a mistake that young dogs only have it. If, however, generally
attacks before the animal arrives at eighteen months old. When it comes on very early, the chances of recovery are very small. It is peculiarly fatal to greyhounds, much more so than to any other kind of dogs. Not the least affecting part of the disease is the tendency of it to recur, which is so marked that it is certain to return unless the treatment is as, either in its mode of attack, or during its continuance. In some cases it commences by purging, in others by retching. Some have cough only, some waste, and others have moisture from the eyes and nose, without any other action. In some there is no moist eyes, dhubbing, and vomiting. Most commonly, however, the common symptom they both of these. Then purging comes on, and the moisture from the eyes and nose from mere mucus becomes pus, or matter. There is also frequently sneezing, with a weakness in the knees. When the disease in this latter case is not speedily removed, universal palsy comes on. Dogs that are attacked, so soon as they begin to recover, quickly, the recovery is extremely doubtful. Many dogs are carried off rapidly by the fits, or by purging; others waste gradually from the running from the nose and eyes, and these cases are always accompanied with great marks of putridity.

The case. In the early stages of the complaint give emetics; they are peculiarly useful. A large spoonful of common salt, dissolved in three spoonfuls of warm water, has been recommended; the quantity of salt being increased according to the size of the dog, and the difficulty of making him vomit; while a dog remains strong, one every third day is not too much. The bowels should be kept open, but active purging should be avoided. In case the complaint should be accompanied with excessive looseness, it should be immediately stopped by balls made of equal parts of gum arabic, prepared chalk, and conserve of roses, with rice milk as food. Two or three grains of James's powder may be advantageously given at night, in cases where the bowels are not affected; and in the cases where the matter from the nose and eyes betokens much putridity, we have witnessed great benefits from balls made of what is termed Friar's balsam, gum guaiacum, and chamomile flowers in powder. In the most popular remedy is the gum, powdered and varied under the name of emulsifier, with instructions for the use of it. Dogs, in every stage of the disease, should be particularly well fed. A seton we have not found so useful as is generally supposed; where the nose is much stopped, rubbing tar on the upper part is beneficial, and when there is much stupidity, and the head seems much affected, a blister on the top is often serviceable.

7413. *Etu.* Dogs are peculiarly subject to fits. These are of various kinds, and arise from various causes. In dogs, frequently are seen convulsions with convulsive fits, which begin with a champing of the mouth and rolling over the water or the ground. Sometimes they will stop their progress, but more generally they prove fatal. *Worms* are often the cause of fits in dogs. These deprive the animal wholly of sense; he runs wild till he becomes exhausted, when he gradually returns again for some time. Convulsive attacks are very frequent, becoming likewise convulsions. Cold thrown over a dog will generally remove the present attack of a fit; and for the prevention of their future recurrence, it is evident that the foregoing account of causes must be attended to.

1414. Inflamed bowels. Dogs are very subject to inflammation of their bowels, from coldness, from cold, or from poison. When inflammation arises from coldness it is in general very slow in its progress, and is not attended with very acute pain, but it is characterised by the want of evacuation and the constipation of which it may be accompanied. An apparent appetite in these cases is not to be made use of are, the removal of the constipation by active purging, clysters, and the warm bath. Calomel with aloes forms the best purge. But when the inflammation may be supposed to arise from cold, kind of sheath inflammation is characterised by violent panting, total rejection of food, and constant sickness. There is great heat in the belly, and great pain; it is also accompanied with great weakness, and the eyes are very red. The bowels should be gently opened with clysters, but no aloes or calomel should be made use of. The belly should be blistered, having first used the warm bath. When the inflammation arises from poison, there is then constant sickness; the nose, paws, and ears are cold; and there is a frequent evacuation of brown or yellow stools. Castor oil should be given, and clysters of mutton broth thrown up but;

7415. Inflamed lungs. Pleurisy is not an uncommon disease among dogs. It is sometimes epidemic, carrying off great numbers. Its attack is rapid, and it generally terminates in death on the third day, by a great effusion of water in the chest. It is seldom that it is taken in time; when it is, bleeding is useful, and blister may be applied to the abdomen and chest.
rabid dogs, which he says is neither a bark nor a howl, but a tone compounded of both. It has been said by some that this disorder is occasioned by heat or bad food; but the fact is that it never arises from any other cause. Rabies is rare in the northern parts of Turkey, more rare in the southern provinces of that empire, and totally unknown under the burning sky of Egypt. At Aleppo, where these animals perish in great numbers, for want of water and food, and by the heat of the sun, or by the climate of America, dogs are never attacked with madness. Blaine knows of no instance of the complaint being cured, although he has, to their fullest extent, the popular remedies of profuse bleedings, strong mercurial and arsenical doses, vinegar, partial drowning, Nightshade, water plantain, &c.; he therefore recommends the attention to be principally directed towards the prevention of the malady.

7449. The preventative treatment of rabies or madness is, according to Blaine, always an easy process in the human subject, from the immediate part being easily detected; in which case by the use of the purgative, or the purgative and prophylactic, it is not easy to detect the eaten parts being generally known. Dr. Meech's powder, the Orenskirk powder, sea-bathing, and you may mention other nostrums are deservedly in disfavour, while those remedies, by which Mr. Grayson has maintained some character. Conceiving that these must all possess some ingredient in common, he was at pains to discover it; and which he has appeared to have realised by obtaining in others the composition of Webb's Watford drink. In this mixture, which is detailed below, he has so far not attempted to be the Juxus or box, which has been known as a prophylactic as long as the times of Hippocrates and Celsius, who both mention it. The detail received below has been administered to three thousand animals of different kinds, as horses, cows, sheep, swine, and dogs; and appears to have succeeded in a very great majority. It is a strong prophylactic in the human subject; but as it would be most imprudent to trust it to alone, where exclusion can be practised, so it will be long before the extent of such power can be ascertained in man. The box preventative is thus directed to be prepared:

Take of the fresh leaves of rue

<table>
<thead>
<tr>
<th>of the fresh leaves of rue</th>
<th>2 ounces.</th>
</tr>
</thead>
<tbody>
<tr>
<td>of sage</td>
<td>1 ounce.</td>
</tr>
</tbody>
</table>

Chop these fine, and boil in a pint of water to half a pint; strain cautiously, and press out the liquor very finely. Mix the two ingredients, add a pint of milk, and boil again to half a pint; strain as before; mix both liquors, which forms three doses for a human subject. Double this quantity is proper for a horse or a cow. Two thirds of the quantity is sufficient for a large dog; half for a middling-sized, and one third for a small dog. Three fifths of the quantity is given on each day, given once or twice. The quantity directed being that which forms these three doses. As it sometimes produces strong effects on dogs, it may be proper to begin with a small dose; but in the case of dogs we hold it always prudent to increase the dose till effects are evident, by the sickness, purging, and unconsciousness of the dog. In the human subject, where this remedy appears equally as efficacious, we have employed any pleasant or active effects; neither are such observed in cattle of any kind. About forty human beings have taken this remedy, and in every instance it has succeeded equally as with animals: but candour obliges us to notice, that in the major part of those cases in which means were used, as the actual or potential cure; nothing was observed.

It is also remarked by the annalist, that the pendulous state of the tongue in what is termed dumb madness, with the existence of a partial paralysis of the under jaw by which they could not bite, having happened to dogs previously wormed, has made the inability to be attributed to this source, but which is wholly an accidental circumstance, and happens equally to the wormed and unwormed. Blaine, on the contrary, asserts, that this is a very frequent and disease in dogs, and is a affection of the skin, either caused by contagion or generated by the animal. The scabby mange breaks out in blotches along the back and neck, and is common to Newfoundland dogs, terriers, pointers, and spaniels, and is the most contagious. The cases are easy to be removed by removing the first excoriations; but the more general the contrary (for both will equally produce it), too full living: then an application should be made to the parts, consisting of sulphur and sal ammoniac; tar, lime-water will also assist. When there is much heat and itching, bleeding and purge. Mercurials sometimes assist, but they should be used with caution, as the dogs do not bear them well.

7450. To prevent canine madness Pliny recommends worming of dogs; and from his time to the present it has had, most deservedly says Daniel, its advocates. He tells us that he has had various opportunities to prove the usefulness of this practice, and recommends the practice. The practice of worming is wholly useless and founded in error; for the existence of any thing like a worm under the tongue is incontestably proved to be false; and that what has been taken for it is merely a deep ligature of the skin, placed there to restrain the tongue in its motions. He also observes, that the pendulous state of the tongue in what is termed dumb madness, with the existence of a partial paralysis of the under jaw by which they could not bite, having happened to dogs previously wormed, has made the inability to be attributed to this source, but which is wholly an accidental circumstance, and happens equally to the wormed and unwormed.

7450. The cat (Felix Catus L.) is distinguished from the lion, tiger, leopard, and others of the genus Felis, by its anneulate tail.

7452. Its habits are thus given by Linnaeus:—"Inhabits woods of Europe and Asia; domesticated everywhere; when tranquil purs, moving the tail; when irritated it is very active, climbs, sprints, emits a fetid odour; eyes shine at night, the pupil by the day a perpendicular line, by night large, round, walks with the front feet bent; breaths in; drinks the water by the mouth; trined, black - fur, mottled, or striated, makes a horrid mewing in its amours; mews after and plays with its kittens; wags its tail when looking after prey; the lion of mice, birds, and the smaller quadrupeds; peaceful among its tribe; eats flesh and fish; refuses sweet things, unless they are collected; the fur is silky; the ears when thrown up, falls on its feet; is not infested with lice; gravid sixty-three days; brings three to nine young, blind nine days; delights in marum, cat-mint, and valerian."

7453. The cat is of great use in the farmery in catching mice, rats, and even birds. It is most desirable to keep them, as their females keep the noisy gallinaceous, and in the adjoining tom-cats is exceedingly annoying.
POULTRY in and yet 10. *7431.

The ferret (Mustela Furo L., fig. 923.) is an animal of the weasel and polecat kind, distinguished by its red fiery eyes.

7430. *It is a native of Africa, but is tamed in Europe for the purpose of catching rabbits. It proceeds twice a year, is gravid six weeks, and brings from six to eight young; smells very feitid. The ferret is very susceptible of cold, and must be kept in a box provided with wool or other warm materials, and may be fed with bread and milk. Its sleep is long and profound, and it awakes with a voracious appetite, which is most highly gratified by the blood of small and young animals. Its enmity to rats and rabbits is unspeakable, and when either are, though for the first time, presented to it, it seizes and bites them with the most frenzied madness. When employed to expel the rabbit from its burrows it must be muzzled, as otherwise it will suck the blood of its victim and instantly fall into a profound sleep, from which it will awake only to the work of destruction, committing in the warren, where it was introduced only for its services, the most dreadful waste and havoc. It is possessed of high irritability, and when particularly excited is attended with an odour extremely offensive.

Chap. IX.

Animals of the Bird kind employed in Agriculture.

7430. Though poultry form a very insignificant part of the live stock of a farm, yet they ought not to be altogether despised. In the largest farm a few domestic fowls pick up what might escape the pigs and be lost; and on small farms and among cottagers, the breeding and rearing of early chickens and ducks, and in some situations the rearing of turkeys and the keeping of geese, are found profitable. There are few who do not relish a new egg or a pancake, not to say the flesh of fowls; and there are some of these comforts which happily can be had in as great perfection in the cottage as in the palace. The various kinds of domestic fowls and birds which are used in agriculture may be classed as gallinaceous, or with cloft feet; anserine, or web-footed; and birds of fancy or luxury. Before proceeding to the first division we shall offer some remarks on poultry hovels.

Sect. I. Poultry Houses and their Furniture and Utensils.

7431. The situation of the poultry house should be dry, and exposed either to the east or south-east, so as to enjoy the sun’s rays in winter as soon as he appears above the horizon. Though in many cases all the commoner sorts of poultry are lodged in the same apartment; yet to be bestow on each species its proper treatment, they ought to be separated by divisions, and enter by separate doors. Apartments for aquatic fowls may be made in part under those of the gallinaceous tribe, and the peacock often prefers roosting on a tree, or on the roof of high buildings, when it forms an excellent watch bird to the poultry-yard or farmery.

7432. Where a complete set of poultry houses are intended, then a situation should be fixed on near or close to the farmery, and with ample space around for the fowls to disperse over in the day-time, and one or more ponds for the aquatic sorts. A space thirty feet by fifty feet may be made choice of for the buildings and yard (fig. 924); the building may be ranged along the north side, and the three other sides enclosed with a trellis or wire fence from six to eight feet in height, and subdivided with similar fences according to the number of apartments. The hen-house (a) and turkey-house (b) may have their roots (c) in part over the low houses for ducks (d) and geese (e), and besides these there may be other apartments (f, g, h) for hatching or newly hatched broods, for fattening, to serve as an hospital, or for retaining, boiling, or otherwise preparing food, killing poultry, and other purposes. A flue may pass through the whole in moist or very severe weather; the walls should be built hollow in the manner already described (7602), which will at the same time be a saving of material; and the windows ought to have outside shutters, both for excluding excessive heats and excessive colds. In every apartment there ought to be a window opposite the door, in order to create a thorough draught when both are opened, and also a valve in the roof to admit the escape of the hottest and lightest air. Every door ought to have a small opening at bottom, for the admission of the fowls when the door is shut. The elevation (fig. 925.) should be in a simple style, and there may be a pigeonry over the central building.
7433. In ordinary cases, where poultry are kept on a farm merely to consume what would otherwise be lost, one or two compartments of the low range of buildings on the south side of the yard are usually devoted to them, or any dry convenient place, according to the general plan of the farmyard.

7434. The furniture or fixtures of the poultry houses are very few; the roost is sometimes a mere floor or loft, to which the birds fly up or ascend by a ladder; at other times it is nothing more than the coping timbers of the roof, or a series of cross battens: but the most approved mode is a series of rough polygonal or angular battens or rods rising in gradation from the floor to the roof, as already explained (2810., and 2812.): the battens placed at the distance herebefore specified, so that the birds when roosting may not inconvenience each other by their droppings. For this purpose they should be a foot apart for hens, and eighteen inches apart for turkeys. The slope of the roost may be about 45°, and the lower part should lift up by hinges in order to admit a person beneath to remove the dung. No flying is requisite in the case of such a roost, as the birds ascend and descend by steps.

7435. Nests are sometimes fixtures, in which case they are nitches built against the wall, not unlike wine bins; where there is more than one tier on the ground floor, each superincumbent range must have a projecting balcony in front of about an even width, with steps of ascent at convenient distances.

7436. A small boiler for preparing food may sometimes be requisite, though on a small scale this may be done in the kitchen. Watering troughs are generally fixed in the yards. In confined situations there should be a large heap of sand, in which the fowls may nest when in order to free themselves from vermin; there should also be a spot composed of gravel, sand, and soft earth, for nearly the same purpose, but more especially for exercising the young chickens. A roof for shelter and protection from the sun may very appropriately be placed over this last compartment, or a part of it.

7437. The utensils are the portable nest, (fig. 925. a.) coops (b, c), portable shelter (d); feeding dishes 926. corn bin for retaining a store of food, egg basket, and feather bags. We avoid enumerating the utensils used in craming, considering that unwholesome and disgusting practice as unfit for the present age.

An improved poultry feeder (fig. 927.) has lately been published in the Transactions of the Highland Society. It is made to hold half a quarter of grain, not one particle of which can be lost. When once filled, it requires no more trouble, as the grain falls down into the receiver below, as the fowls pick it away; and the covers on that, which are opened by perches, and the iron cover above, which is secured by a padlock, completely keep the grain from the rain, so that the fowls get it always quite dry; and as nothing less than the weight of a hen on a perch can lift a cover on the lower receiver, sparrows, and other small birds, are completely excluded, whilst the small cross bars through which the fowls pick prevent cattle and other large animals from getting at the grain. It is astonishing with what facility the fowls learn to keep upon the perch, and so open the cover of the receiver which covers the grain.

Sect. II. Gallinaceous Fowls, their Kinds, Breeding, Rearing, and Management.

7438. Under the order Gallinææ are included the common hen, turkey, Guineæ, and peacock; and we shall here treat of each of these birds in succession.

7439. The different species of fowls, that is, of cocks and hens, inhabit in their native state the continent and islands of Asiatic India. Naturalists have not agreed whether these numerous species, which in a domesticated state, have originated from one or from two species. M. Ten- minck considers the Bankiva cock (Gallus Bankivæ) as the origin of our domestic poultry; while others think they may have sprung from the Jungle cock (fig. 928. G. Senaurath), still found in the greatest plenty in the forests of India. The term chicken is applied to the female young of gallinaceous animals till they are four months old; afterwards they are called pullets, till they begin to lay, when they become hens. The male is a chicken till he is three months old, then he is a cock bird till the age of twelve months, when he becomes a cock; unless, indeed, he has been artificially deprived of the faculty of procreation, when, he becomes a capon; and when the ovariun is taken from a pullet or hen, she is called a hen capon.

7440. The varieties of a bird so long under culture may naturally be expected to be numerous; the most esteemed in Britain, at the present time, are the following:—

7441. The common dunghill cock and hen (fig. 929.), rather small in size, delicate in limb, colour generally red or brown; flesh white, and su-
prior to that of any other variety for richness and delicacy of flavour; eggs small, fine shaped, and extremely delicate: the chickens are difficult to rear from their pugnacious dispositions. The game cock has long been a bird both of cruel and curious sport in this as well as other countries; but the taste for these amusements, like that for others suited to times of comparative leisure and ignorance, is now happily on the decline in Britain.

929. The Dorking cock and hen (fig. 743), called from the town in Surrey of that name, is the largest variety; shape handsome, legs long and capacious; legs short, five claws on each foot; eggs large, and lays abundantly; colour of the flesh inclining to yellowish or ivory. Both hens and cocks often made into capons.

930. The Poland cock and hen (fig. 744) were originally imported from Holland. The colour shining black, with white tops on the head of both cock and hen; head flat, surmounted by a fleshy protuberance, out of which spring the crown feathers, or top, white or black, with the fleshy king David's crown (the celestial in heraldry), consisting of four or five spikes; their form plump and deep; legs short, feet with five claws; lay abundantly; are less inclined to set than any other breed; they fatten quickly, and are more juicy and rich than the Dorking.

931. The every-day cock and hen is a subvariety of the above, of Dutch origin; they are of smaller size, and said to be everlasting layers. Their tops are large, and should be periodically clipped near the eyes; otherwise, according to Mowbray (Treatise on Domestic Fowls, 24. and 115.), they will grow into the eyes of the fowls and render them very subject to alarm.

932. The bantam cock and hen (fig. 745) is a small Indian breed, valued chiefly for its grotesque figure and delicate flesh. Mowbray mentions a subvariety, extremely small, and as smooth-legged as a game fowl. From their size and delicacy they are very convenient, as they may always be used as substitutes for chickens when small ones are not otherwise to be had. They are also particularly useful for sitting upon the eggs of partridges and pheasants, being good of which the more common is re-

933. The Chittagong or Malay hen (fig. 934) is an Indian breed, and the largest variety of the species. They are in colour striated, yellow, and dark brown; long necked, serpent-headed, and high upon the leg; their flesh dark, coarse, and chiefly adapted to soup. They are good layers; and being well fed produce large, substantial, and nutritious eggs; but these birds are too long-legged to be steady sitters.

947. The black-bag, or Duke of Leeds' breed, was formerly in great repute, but is now nearly lost. It is sometimes to be met with at Wokingham (Oakingham), in Berkshire, and is so large, and the flesh so white, firm, and fine, as to afford a convenient substitute for the turkey.

948. The improved Spanish cock and hen is a cross between the Dorking and Spanish breed, also to be found in and around Wokingham. It is a large bird with black plumage, white and delicate flesh, the largest eggs of any British variety, and well adapted for copons.
Breeding. The commonest variety is easily procurable; but the setters must either be procured from those parts of the country where they are usually bred, or from the poulterers and bird fanciers in large towns, and especially in London. It should be a general rule to breed from young stock; a two-year-old cock, or stag, and pullets in their second year. Pullets in their first year, if early birds, will, indeed, produce many eggs as ever after; but the eggs are small, and the birds do not breed so readily as the setters. Hens are in their prime at three years of age, and decline after five, whence, generally, it is not advantageous to keep them beyond that period, with the exception of those of capital qualifications. Hens with a large crop, or which crown the cock, are generally deemed inferior; but I have had hens with large crops, who have been the most continually successful in which I have kept them. Legged fowls are often of a tender constitution, and always inferior in the quality of their flesh, which is of a loose fibrous texture, and ordinary flavour.

The dryness of hens is observable in the fresh and florid colour of the comb, and the brightness and dryness of the eyes; the nostrils being free from any discharge, and the healthy gloss of the plumage. The most useful cock is generally a bold, active, and savage bird, sometimes cruel and destructive in his fits of passion, if not well watched, to his hens, and even to his offspring. Hens above the common size of the pullets are remarkable for the elegant air they exhibit; the softer feathers of the tail plumes are generally paler than the rest. A large comb and gills, dulness of colour, and a sort of downy stiffness in the feathers, and length and size of talons, the scales upon the legs becoming large and prominent. The junction of the hen to one cock should be from the extreme number, with a view of making the utmost advantage. Ten and even twelve hens have been formerly allowed to one cock, but the produce of eggs and chickens under such an arrangement will seldom equal that to be obtained from the smaller number of hens. Everyone is aware how the spring is the best season to commence breeding with poultry, and in truth it scarcely matters how early, presupposing the best food, accommodation, and attendance, under which hens may be suffered to sit in January.

The contact of the cock towards his hens is generally of the kindest description, and sometimes, as in the Polish breed, so remarkably so, as to be quite incredible to those who have not witnessed it. It is not an uncommon occurrence, however, for the cock to take an antipathy to some individual hen; when it continues for any length of time it is best to remove her, and supply her place by another, taking care that the stranger be not bewildered by the hens. Spare coops or houses will be found useful on such occasions.

The change of a cock, from death or accident, is always attended with interruption and delay, as it may be some considerable time before the hens will associate kindly with their new partner; and until then they may prove dull and unactive from the change. What happens with cocks of the superior breeds, purchased from the London dealers, in whose coops they have been kept in such a high state of temperature, that they are unable to endure the open air of the country, is a subject of no little curiosity. Such hens, if removed in an early stage of their turn, become indolent,以便 turn away from the nest, are liable to become aguish, torpid, and totally useless; perhaps in the end, turning roupy or glaucered. The only method of safety in this case is to keep such a cock in the house, upon turning the best and most nourishing food, upon the hens to him several times in the day, and permitting him to be abroad an hour or so, the weather being fine, until, in a few weeks, he shall be accustomed to the air.

In making the nests, soft and short straw is to be preferred; because, the straw being long, the hen, on removing the nest, will be liable to draw it out with her own weight. It is ascertained, will breed and lay eggs without the company of a cock; of course, such eggs are barren.

Eggs for setting should never exceed the age of a month, the newer to be preferred, as nearly of a size as possible, and of the full middle size; void of the circular flaw, which indicates the double yolk, getting which, though thoughtless, nor should there be any roughness of the shell, according to the size of the hen, from nine to fifteen, an odd number being preferable, on the supposition of their lying more close. The eggs to be marked with a pen and ink, and examined when the hen leaves her nest, in order to detect any fresh ones which the boy may take, and which should be immediately taken from her, as they, if at all, would be hatched too late for the brood. It is taken for granted the box and nest have been made perfectly clean for the reception of the hen, and that a new nest has not been sluggishly or sluttishly thrown upon an old one, from the fifth of which vermin are propagated, to the detriment of the young birds. To prevent the escape of the eggs, the box should be cleared away the instant of discovery, and the remaining washed with warm water, and quickly replaced, lest they adhere to the hen, and be drawn out of the nest; if necessary, the hen's feathers may also be washed, but always with warm water.

With respect to the capriciousness of some hens, in the article of setting, it is a risk which must be left to the judgment of the attendant, who has to determine whether the hen which appears desirous of setting may be safely trusted with eggs. Leaving a number of eggs in the nest is an enticement. Very frequently, the hen will clutch, and appear engrossed for incubation; if, in the course of two or three hours to add others, will be seldom to be found, but for eggs in the winter, such being scarcely fuller of meat than Christmas. And then, probably, may not begin to lay full April, and not last not more than twenty or thirty eggs. In general, it is most profitable to dispose of hens whilst they are yet eatable or salable for that purpose, which is in the spring of the third year. Nor do delicate white hens lay so many eggs as the hardy in the second season, perhaps with advantage to shade, required with and shelter, particularly by night. Moult, or the casting and renewal of feathers, lasts with its effects from one to three months, according to the age and strength of the bird. Whilst under this natural course, poorly fed, and too long kept in the nest, it is as for breeding, is thoughtless, whilst shading their feathers in the spring. The regular moult of full-grown fowls begins in the autumn.

In some hens the desire of incubation is so powerful, that they will repeat it five or six times in the year; in others it is so slight, that they will probably not sit more than once or twice in the season. A skilful breeder will take advantage of these qualities, and provide abundance of eggs from the one variety, and of chickens by means of the other. Hens, when sitting, drink more than usual; and it is an old maxim to one cock that he will drink constantly before he sits when in this state, and food (say corn) at least twice a day. The time of incubation is twenty-one days.

Hatching. The chicken, hitherto rolled up like a ball, with its bill under the right wing, like a bird asleep, begins generally on the morning of the twenty-second day to commence its way through the shell; neither the hen, nor the can art of man, with safety render them aid in this very interesting and wonder-ful operation. The parental affection of the hen, as Mowbray and Parmentier have observed, is always
intensely increased, when she first hears the voice of the chicks through the shells, and the strokes of their little bills against them. The signs of a need of assistance, the former author observes, are, the egg being partly pecked, and the efforts of the chick discontinued for five or six hours. The shell may then be broken cautiously, and the body of the chicken carefully separated from the viscous fluid which lines it. Réaumur gives it as his opinion, that no aid ought to be given to any chicken but those which have been near twenty-four hours employed without getting forward in their work.

761. The chickens first hatched should be taken from the hen, lest she be tempted to leave her task unfinished. Those removed may be secured in a basket of wool or soft hay, and kept in moderate heat, if the weather be cold, near the fire. They will require no food for many hours, even four and twenty, should it be necessary to keep them so long from the hen. The whole brood being hatched, the hen is to be placed under a coop abroad, upon a dry spot, and, if possible, not within reach of another hen, since the chickens will mix, and the hens are apt to malt or destroy those which do not belong to them. Nor should they be placed near numbers of young fowls, which are likely to crush young chicks under their feet, being always eager for the chicken's meat. The first food should be split grits, afterwards tail wheat; all watery food, soaked bread, or potatoes, is improper. Eggs boiled hard, or curd chopped small, are much approved as first food. Their water should be pure and often renewed; and there are convenient pans made, in such forms that the chickens may drink without getting into the water, which often, by wetting their feet and feathers, numbs and injures them. A basin whelmed in the middle of a pan of water will answer the end, the water running round it generally; and, independently of situation, and the disposition of the hen, there is no necessity for cooping the brood beyond two or three days; but they may be confined as occasion requires, or suffered to range, as they are much benefited by the scratching and foraging of the hen. They must not be let out too early in the morning, or whilst the dew remains upon the ground, far less be suffered to range over the wet grass, one common and fatal cause of disease. Another caution is of the utmost consequence, to guard them watchfully against sudden unfavourable changes of the weather, more particularly if attended with rain. Nearly all the disorders of gallinaceous fowls arise from cold moisture.

762. For the period of the chickens quitting the hen, there is no general rule; the most certain is, when the hen begins to roost, leaving them; if sufficiently forward, they will follow her; if otherwise, they should be secured in a proper place, the time having arrived when they are to associate with the young poultry, as nearly of their own age and size as possible, since the larger are apt to overrun and drive from their food the younger brood.

763. Hatching by artificial heat is an Egyptian practice, mentioned by Diodorus and Aristotle, and was brought into notice about the middle of the eighteenth century, by Le Bé in his "Art de faire écair, &c. des Oiseaux domestiques." The requisite degree of heat is 90 degrees, which is supplied by fire, steam, hot water, or fermentitious substances; after hatching, the birds are placed in a cage, in which is placed a lamb-skin suspended from the roof of a box, and enclosed by a curtain of green bâize; or, according to Parmentier, they may be placed upon a canvas, which, after being prepared for receiving pleasure from feeling the chickens under its belly, by depriving it of the greater part of the feathers and excoriating, is to be confined with them in the same coop, and after being fed together for a day or two, it is said the capon will become an excellent nursing mother. Excepting as matter of curiosity, however, it is not at present worth while to either hatch or rear chickens artificially in this country. Whether Réaumur's mode of hatching be adopted, or Mrs D'Oyly's of depriving hens of their chickens as soon as hatched, and thus causing one hen to hatch five or six broods in succession, the human attention required, and the risk of failure are so great, that the same modes, under all the present circumstances, are such as are natural. Where it is tried for experiment or curiosity, the heat of tan or dung is more likely to prove steady than that from smoke, air, or steam, probably even than that of hot water, successfully tried, however, and, we believe, still practised in the neighbourhood of Paris. An enclosure in the middle of a box, with a curtain or curtain, under which might serve at once to hatch and rear early chickens: and such a mode of rearing, at least in the winter season, certainly deserves the attention of those who are curious in having this luxury in February and March. In 1822 or 1823 some interesting experiments were exhibited by Mr Barlow at the Egyptian Hall, London, relative to an improved method which he had invented, of hatching eggs by artificial heat. The method, and the machine necessary to practise it, seem to have come very little into use.

764. The incubation of chickens by hot water is the invention of M. Bonnemain, physiocrate, of Paris. In 1777, and still alive when we were in that capital in 1828. Chickens hatched in this way at St Germain's, under M. B.'s direction, it is said, supplied the table of Louis XIV. The boiler of the apparatus is called a calorifère, (color, heat, and ferre, to bear,) and consists of a small boiler (fig. 934 a), a box or building (b) for hatching the eggs, a cage or coop (c) for rearing the chickens, tubes (d) for circulating the hot water, a supply tube and funnel (e), and a safety tube (f). Supposing the water heated in the boiler, it will rise by its specific levity through the tube (a, d), move progressively through all the tubes, and return again to the boiler by the tube (g), which is inserted in the lid like the other, but passing through its lower part (h). This circulatory movement, once commenced, continues so long as the water is heated in the boiler, because the temperature is never equal throughout all parts of the apparatus. We may readily conceive that a perfect equality of temperature can never exist, on account of the continual loss of heat, which escapes from the exteriors of all the tubes. Meanwhile, the temperature of the air en-
closed in the box differs but little from that of the numerous tubes which traverse it; and as the ends of the tubes on the outside of the box afford little surface to be cooled by the surrounding air, so the force of the circulation, which is always in the ratio of the difference between the temperature of the water and the cabin, increases it, of course, to a still greater extent. In having expended a large portion of its heat on the outside of the box, in maintaining a gentle heat in the cage (c) adjoining it. We see, therefore, that the more the water is cooled which passes through the last circumvolutions of the tubes, the more active is the circulation in all parts; and, consequently, the more this heat, which heads off the condensation of the tubes which have been allowed to prevent the loss of heat as much as possible, the boiler, and all those parts of the tubes which are placed on the exterior of the box, are enveloped in lists of wooden cloth. M. Bonne main having thus applied this arrangement in so much skill, and with such admirable skill, as to enable the cold to be thrown off varying scarcely so much as half a degree of Réaumur's thermometer; but, as if it were not sufficient to have thus far resolved the problem, he contrived that this degree of temperature in all parts of the stove should be maintained at that point which was found most favourable for promoting incubation. It was by means of a circular, or the attraction or repulsion of the fire that this was conveniently rendered. A regulator is founded on the unequal dilatation of different metals by heat. A movement is communicated near the axis of a balanced lever, which lever transmits it by an iron wire to a register in the ash-pan dots. 

Combination of these means in this piece of machinery are fully described and delineated in Gill's Technological Register (Feb. 1828, p. 70).

7455. When we would hatch chickens by hot water, we light the fire and raise the temperature till we obtain that degree of heat in the box which is fitted for incubation; we then place the eggs near to each other, all of which must be of the same kind, and from them (c, fig. 7) we take off, as convenient not to cover, on the first day, more than a twentieth part of the surfaces of the shelves, and to add every day, for twenty days, an equal quantity of eggs; so that, on the twenty-first day, the quantity of eggs first placed will be for the greatest part, hatched; so that we may obtain every day nearly the same number of chickens; but which may, nevertheless, be occasionally regulated by the particular season of the year.

7456. During the first days of incubation, whether natural or artificial, the small portion of water contained within the substance of the egg evaporates through the pores in its shell: this is replaced by a small quantity of air, which is necessary to support the respiration of the chick; but as the atmospheric air which surround the eggs in the box at that degree of temperature is either completely dry, or but little moistened, the chick would either suffer, or be destroyed. An aqueous vapour which exudes from the breathing of the old fowls while hatching, in some degree prevents this ill effect; but, nevertheless, in dry seasons, the vapour is hardly sufficient; and thus, in order that the eggs may be better hatched in dry seasons, the hens cover them with the earth of the floor of the greatest partual incubation, and keep the air in the incubating vessels, as plates (k, l), filled with water. When the chickens are hatched, they are removed from the stove, and carried to the cage (e), where they are fed with milk, and nestle under a sheep's skin, which is suspended over them. They are allowed to remain under these circumstances as the chickens as they are hatched each day, in order to modify their nourishment agreeably to their age.

Artificial incubation is exceedingly useful in furnishing young fowls at those seasons when the hens will not sit, and, in some situations, to produce, or, as we may say indeed, to manufacture a great number of fowls in a small space. (Gill's Technological Repository, No. vii. p. 73. as quoted in Gard. Mag. vol. iv. p. 307.)

7457. The products of the cock and hen are eggs, feathers, and the carcass.

7458. Eggs become desiccated, and, in consequence, lose great part of their substance and nutritive quality, by keeping; and every body knows the value of a fresh-laid egg. They retain their moisture and goodness, however, three or four months, or more, if the pores of the shell be closed and rendered impervious to the air, by some unceasing application. We generally anoint them with mutton suet melted, and set them on end, wedged close together, in bran, stratum super stratum, the containing box being closely covered. Laid upon the side, the yolk will adhere to the shell. They thus come into use, at the end of a considerable period of time, in a state almost equal to new-laid eggs, for consumption; but ought not to be treated for incubation, excepting in the case of the imported eggs of birds in the cage.

7459. The largest eggs will weigh two ounces and a half, those of the Chittagong hen perhaps three ounces.

To promote feodimity and great laying in the hen, nothing more is necessary than the best corn and fair water. At this rate, the imported cultivated barley has occasionally a good effect, whilst the hens are kept constantly employed; but if continued too long, it promotes a miliary bone and scrofulous Colsing in the cold season, and also tox and ale, as every henwife well knows. It must be noted, that nothing is more necessary towards success in the particular of obtaining plenty of eggs, than a good attendance of cocks, exercised in the same season, and to be sure kept; also especially, that be be in season; as some are unsexilly useless. Buffon, says a hen well fed and attended will produce upwards of one hundred and fifty eggs in a year, besides two broods of chickens. Mowbray observed, that a hen generally cackled three or four days previously to laying; and that some half-bred game hens began to lay as soon as their chickens were three weeks old; the other two weeks or two, under the notion of availing themselves for the task imposed on them; the state of their fat; a practice which, however, seldom succeeds, since the fowls generally pine for their loss of liberty.
and slighting their food, lose instead of gaining additional flesh. Such a period, in fact, is too short for them to become accustomed to confinement.

747. **Feeding-horns** should be warm and airy, with earth floors well raised, and capacious enough to accommodate twenty or thirty fowls, or slightly littered down, and the litter often changed. Such gravel and a little lime rubbish should be placed in different places, and often changed. A sufficient number of troughs, for both water and food, should be placed around, that the stock may feed with as little trouble as possible. Perches in the form of steps, or from ten to twelve inches apart, should be provided for those birds which are inclined to perch, which few of them will desire after they have begun to fatten, but which helps to keep them easy and contented until that period. In this mode fowls may be fattened to the highest pleasing state, their flesh growing equal in quality to that of the barn-yard fowls.

To suffer fattening fowls to perch is contrary to the general practice, since it is supposed to bend and deform the breast-bone; but as soon as they become heavy and indolent from feeding, they will rather incline to rest in the straw; and the liberty of perching in the commencement of their coop- ing will be the means of retaining them ten to twelve weeks longer. Moreover, of considerable growth will have many of them become already crooked from perching whilst at large, although much depends upon form in this case, since we feed aged cocks and hens of the middling size, and with the breast bone which will improve, that of the fattened hen, will make the best of them; it being extremely difficult, and often impossible, to fatten long-legged fowls in coops, which, however, are brought to a good weight at the barn-door.

748. In the choice of full-sized fowls for feeding, the short-legged and early hatched are not where a proper and uniform form of feathering is desired and obtained the true harking breed approaches the nearest to such model. Of course the smaller breeds and the game are the most delicate and soonest ripe. The London chicken butchers as they are termed, or poulterers, are said to be of all others the most experimental; they keep up a coop of fowls with a bird for each perch, and have the advantage of being able to judge, in the short space of a fortnight, using so much grease, and that perhaps not of the most delicate kind, in the food. In the common way this business is often badly managed, fowls being huddled together in a small coop, tearing each other to pieces, instead of enjoying that repose which alone can ensure the wished for results. By this method the cocks are stochen and passed in their own excrement, that their flesh actually smells and tastes of it when smoking upon the table. Where a steady and regular profit is required from poultry, the best method, whether for domestic use or sale, is constant high kind of feeding, which will not only improve the table with the nearest approach to reality, but have the attention, but their flesh will be superior in juiciness and rich flavour to those which are fattened from a low emaciated state. Fed in this mode, the spring pullets are particularly fine, and at the same time most nourishing and restorative food. The pullets which have been fattened for the nest, will lay plentifully through the following autumn, and not being intended for breeding stock, the advantage of their eggs may be taken, and themselves disposed of thoroughly for fat in the above month, about which period their laying will be finished. Instead of giving ordinary and tall corn to fattening and breeding poultry, it will be found most advantageous to allow the heaviest and best partakers the confined pullets upon a level with those fed at the barn-door, where they have their share of the weightiest and fittest flesh. This high feeding shows itself not only in the size and flesh of the fowls, but in the size, weight, and substantial goodness of their eggs, which being the valuable part of all. However, they may be further domestic in use than three of the latter. The water also given to fattening fowls should be often renewed, fresh and clean; indeed, those which have been well kept will turn with disgust from ordinary food and water.

749. Barley and wheat are the greatest dependences for chicken poultry; oats will do for full-grown hens and cocks, but are not so good as barley; both, when they have their nil of corn, will eat occasionally cabbage or beet leaves. Steamed potatoes and oatmeal mixed together make an excellent mess, but must not be given in great quantities, otherwise it renders the flesh soft and flabby.

750. **Cramming.** Barley and wheat meal are generally the basis or chief ingredient in all fattening mixtures for chickens and fowls; but in Sussex ground oats are used, and their oats are in higher estimation for fattening than elsewhere, many large hogs being fattened with them. In the report of that county, the Rev. Arthur Young says, "North Chappel and Kinsford are famous for their poultry; they are fattened there to a size and perfection unknown elsewhere. The food given them is ground oats made into gruel, mixed with hog's grease, sugar, pepper, and salt, and the unsalted; these fowls are kept three weeks, and crammed morning and night. The pot-liquor is mixed with a few handfuls of oatmeal and boiled, with which the meal is kneaded into crams or rolls of a proper size. The fowls are put into the coop two or three days before they are to be crammed, which is done in a very easy manner. These fowls, full grown, weigh seven pounds or more; the average weight of five pounds; but these are instances of individuals double the weight. They were sold for the time of the survey (1829) at to four and five shillings each. Turner, of North Cappel, tenant of Lord Egremont, crams the greatest number of birds per annum. Great art and attention is requisite to cut to the capital, and numbers are destroyed in the operation."
or nourishing, as those fattened upon more simple and substantial food; as, for example, meal and milk, without the addition of either treacle or sugar. With respect to the first point, we have already observed, to be the tenderest and of indelicate flavour. Nor is any advantage gained, excluding the commercial one.

7483. The method of cramming by confining in a box the size of the body of the fowl, and allowing its head and vent to project for introduction and ejection; of blinding the bird for this purpose; or of nailling it to the board; and also the mode of forcing down liquid food by a particular kind of pump, worked by the foot of the feeder; all these and other cruel practices we wish we could abolish in practice, and obliterating them, inscribed page.

7484. Castration is performed on cocks and hens only in some districts, and chiefly in Berkshire and Sasse. The usual time is when they have left the hen, or when the cocks begin to crowd, but the earlier the better. It is a barbarous practice and better omitted. Several supposed harmless, by which, it is said, will not roost on the same perch with them. The Chinese mode of making capons is fully described and illustrated with cuts in the Farmer's Magazine, vol. vi. p. 46.

7485. Pinioning of fowls is often practised to restrain them from flying too high, or from flying over fences, i.e., is a more convenient than the cutting their wing feathers only. But in the ordinary methods of merely exciting the passion, it is frequently fatal; and almost always so to full-grown birds or fowls, by their bleeding to death.

To prevent this in the long-winged tribes, as ducks, geese, &c., pass a thread needle through the wing, and secure both its ends, making a ligature with the thread across the larger bone, and returning it on the outside of all, the whole tied with a string. This is usually performed by a ligature confined to the surface only. After the blood-vessels have been thus secured, cut off the portion of wing beyond the ligature with scissors or shears. In the Gallinaceas or short-winged tribes, as cocks, hens, &c., the operation is rendered safer by being performed on the beginning of the next joint (b), making the ligature embrace all the vessels between these two bones by passing it twice through, and seldom in any individual the ligature around the whole of that part of the wing generally. In this way also birds which have been accidentally winged in shooting may be preserved.

7486. The turkey (Meleagris Gallipavo L., fig. 936.) is a native of America, and was introduced into this country from Spain soon after the discovery of the former country. The colour in the wild state is black, but domestication has produced great variety.

7487. In a state of nature they are said to parade in flocks of five hundred, feeding, in general, where abundance of mites are to be found, the seed of which and of a small red acorn is their common food in the American woods. They get fat in a wild state, and are soon run down by dogs. They roost on the highest trees, and since the clearing of extensive tracts in America, have become rare in many places; their anticipatory anything of a red colour is well known. In this country they are supposed to be of a tender constitution, which only applies to them when young; for when grown up they will live in the woods individually, and passing the winter round the whole of that part of the woods. The turkeys differ from the common hen in never scratching for her chickens, leaving them entirely to their own instinct and industry; neither will they fight for their brood, though vigilant in the discovery of birds of prey, when they will call their chickens together by a particular cry, and run with considerable speed. Hence, when not confined within certain limits, they require the attendance of a keeper.

7490. Turkey cocks should be withdrawn from the nest as soon as hatched, and kept very warm by warming one or two warm lamps in the room, or raising them under an ordinary lamp. Various nostrums are recommended to be given and done at this season, as a peppercorn and a tea-spoonful of milk, immersion in cold water, &c. Mowbray wisely rejected all these unwholesome practices, and recommended, by giving currant and hard eggs, or currant and barley meal kneaded with milk, and fed with clear water rather than milk, as he found the last often affected them. A sort of vernicelli, or artificial worms, made from pulling boiled meat into strings, he found beneficial for every species of gallinaceous turkey. Two great objects are, to avoid superfluous moisture, and to maintain the utmost cleanness from the printed pinces as little stop food is given as possible. A very frequent diet of smelling and water. The feed should be daily given as green food, but not snails or worms as scouring, and no oats; nettle seed, clover, rue, or wormwood gathered, as recommended by the cler housewives. Water is generally preferable to milk. Water is generally preferable to milk, and after weather is favoured the hen is crossed. If the hen is crossed, and there is no weather, the cock is crossed. To the last day and night, for the first six weeks, she is kept within doors. After this the hen may be cooped a whole day externally for another fortnight, to harden the chickens; and afterwards they may be left to range within certain limits, or tended by an old man or woman, being fed at going out in the morning and returning in the evening. Their ordinary food may be that of cold milk and water. They prefer roosting abroad upon high trees in the summer season, but that cannot generally be permitted with a view to their safe keeping.

7491. Palitting. Soiled barley, or barley and wheat-meal mixed, is the most approved food; and the general mode of management is the same as that of the common cock and hen. They are generally fed so as to come in at Christmas, but they may be fattened early or late. Sometimes though, but rarely, they are caponized. Buffon says, the wild turkey of America has been known to attain the weight of sixteen pounds; the Norfolk turkeys are said sometimes to weigh twenty and thirty pounds; but Mowbray says,
he never made any higher than fifteen pounds ready for the spit. The living and dead weight of a turkey are as 21 to 14.

Feathers. Turkeys are sometimes plucked alive, a barbarous practice which ought to be laid aside. Parmentier proposed to multiply the breed of white turkeys in France, and to employ the feathers found on the lateral part of the thighs instead of the plumes of the ostrich.

The Guinea hen (Numidia Mcleagris L., fig. 937.) is found in a wild state only in Africa, from whence it has been diffused over every part of Europe, the West Indies, and America. In a state of nature these birds associate in flocks of two or three hundred. They delight in marshy places, but always perch during the night in trees, or high situations. It is bigger than a large cock, and is active, restless, and courageous; and will even attack the turkey, though so much above its size.

The properties of the pheasant and the turkey have been said to be united in this bird; its flesh is more like that of the pheasant than that of the common cock and hen both in colour and taste, and is reckoned a very good substitute for the former bird. It is also very prolific, and its eggs are nourishing and good. It assimilates perfectly with common fowls in its artificial habits and kinds of food; but it has this peculiarity—that the cocks and hens are so nearly alike, that it is difficult to distinguish them, and it has a peculiar gait, and cry, and chuckle.

The peacock (Pavo cristatus L.) is a native of India, and found in a wild state in Java and Ceylon, where they perch on trees like the turkey in America. The age of the peacock extends to twenty years, and at three the tail of the cock is full and complete. The cock requires from three to four hens; and where the country agrees with them, they are very prolific, a great ornament to the poultry yard and lawns, and useful for the destruction of all kinds of reptiles. Unfortunately, they are not easily kept within moderate bounds, and are very destructive in gardens. They live on the same food as other domestic fowls, and prefer barley. They are in season from February till June; but though a peacock forms a very showy dish, the flesh is ill-coloured and coarse, and they are therefore kept more as birds of ornament than of use.

The crested curassow (Crax Aléctor L., fig. 938.) is a beautiful and majestic bird, nearly the size of a turkey; it is common in some parts of tropical America, and is mentioned as being abundant in Paraguay. In those countries it is tamed, and readily associates with the other domestic poultry. Like most gallinaceous birds, it lives in flocks of about a dozen, feeds upon Indian corn, rice, and other grain during the day, and roosts on high trees at night.

Its size, disposition, and the delicacy of its flesh, all recommend our attempting to domesticate it in this country.

Sect. III. Anserine or Aquatic Fowls.

The order anseres comprehends the duck, goose, swan, and buzzard. Under a regular system, Mowbray observes, it would be preferable to separate entirely the aquatic from the other poultry; the former to have their houses ranged along the banks of a piece of water, with a fence, and sufficiently capacious walks in front; access to the water by doors, to be closed at will. Should the water be of considerable extent, a small boat would be necessary, and might be also conducive to the pleasure of angling.

The duck (Anas Boscas L., fig. 939.) is a native of Britain, and found frequenting the edges and banks of lakes in most parts of Europe. The flesh of this and various other species of the duck is savory and stimulating, and said to afford preferable nourishment to that of the goose, being less gross, and more easily digested. The flesh of the wild duck, though more savoury than that of the tame, is reckoned still more easy of digestion. The ancients went even beyond our greatest modern epicures in their high esteem for the flesh of the duck; and Plutarch asserts, that Cato preserved his whole household in health by dieting them on duck's flesh.

Varieties and species. There are the Rhone, the Aylesbury, the canvas-backed, and the Muscovy.

The English duck, particularly the white variety, especially when they chance to have light-coloured flesh, are never of so
high and savoury flavour as the darker colours. Muscovy, and
other foreign species of the duck, are kept rather out of cu-
ristose than for the table.
7494. The white Egyptian is a beneficial and ornamental
stock, matching well in colour with the domestic geese. They
are said to be early breeders.
7493. The Muscovy duck (A. moschata) is a native of Brazil,
but domesticated in Europe. It is a
curious dark-coloured bird, distinguished by its naked face, kept more out of curiosity than use; to be re-
ained in any place, they must be reared from the egg, otherwise they will fly away
7501. Breeding. One drake is generally put to five ducks; the duck will cover from eleven to fifteen
eggs, and her term of incubation is thirty days. They begin to lay in February, are very prolific, and are
apt, like the Turky, to lay abroad, and conceal their eggs, by covering them with leaves or straws. The
duck generally lays by night, or early in the morning: white and light-coloured ducks produce similar
eggs; and the brown and dark-coloured ducks, those of a greenish blue colour, and of the largest size in
setting ducks, it is considered safest to put light-coloured eggs under light ducks, and the contrary; as
there are instances of the duck turning out with her bill those eggs which were not of her natural
colour.
7505. During incubation, the duck requires a secret and safe place, rather than any attendance, and
will, at nature’s call, cover her eggs, and seek her food, and the refreshment of the waters. On hatching,
there is not often a necessity for taking away any of the brood, barring accidents; and having hatched,
let the duck retain her young upon the nest her own time. On moving her with her brood, prepare a coop
upon the short grass, if the weather be fine, or under a shelter, if otherwise; a wide and flat dish of water,
to be renewed, standing at hand; barley, or any meal, the first food. In rainy weather particularly,
it is useful to clip the tails of the ducklings, and the surrounding down beneath, since they are else apt to
dragge and weaken themselves. The duck should be cooped at a distance from any other. The period
of her confinement to the coop depends on the weather and the strength of the ducklings. A fortnight
seems the longest time necessary; and they may be sometimes permitted to enjoy the pond at the end of
a week, but not for too great a length at once, host of all in cold wet weather, which will affect, and cause
their feet to appear rough and dragged. In such case they must be kept within a while, and have
an allowance of bean or pea meal mixed with their ordinary food. The meal of duck-wheat and the
farmer is then proper. The straw beneath the duck should be often renewed, that the brood may
have a dry and comfortable bed, and the mother herself, when in good case without an ample
allowance of which ducks are not to be reared or kept in perfection, although they gather so much
abroad.
7506. Duck eggs are often hatched by hens, when ducks are more in request than chickens; also as
ducks, in unfavourable situations, are the more easy to rear, as more hardy; and the plan has no objection
in a confined place, and with a small stock, without the advantage of a pond; but the hen is much
distressed, as is sufficiently visible, and, in fact, injured, by the anxiety she suffers in witnessing the
support and suffer the children venturing upon the water.
7507. Ducks are fattened, either in confinement, with plenty of food and water, or full as well restricted
to a pond, with access to as much solid food as they will eat; which last method is preferable. They
fatten speedily, in this mode, mixing their hard meat with such a variety abroad as is natural to them,
more particularly, if already in good case; and there is no check or impediment to their from pining, but
every mouthful tells and weighs its due weight. A dish of mixed food is preferable to white corn, and
may remain on the bank, or rather in a shed, for the ducks. Barley, in any form, should never be used
to fatten ducks or geese, since it renders their flesh loose, woolly, and insipid, and deprives it of that high
savory flavour of brown meat, which is its valuable distinction; in a word, rendering it chickenny, not un
like in flavour the flesh of ordinary and yellow-legged fowls. Oats, whole or bruised, are the standard
fattening material for ducks and geese, to which may be added pea-meal, as it may be required. The
housewife is enabled to mix up the duck food under confinement; but it is obvious, whilst they have the same
affected by ducks which have a range; and they will thrive so much on that provision, that the quantity of
fat will be inconvenient, both in cooking and upon the table. Ducks so fed are certainly interior in
delicacy, but the flesh eats high, and is far from disagreeable. Fed on butcher’s offal, the flesh resembles
wild fowl in flavour, with, however, considerable inferiority. Offal-fed duck’s flesh does not emit the
abominable stench which issues from offal-fed pork. When live ducks are plucked, only a small quantity
of down and feathers should be taken from each wing.
7508. Decoys for wild ducks. Wild ducks, and other aquatic birds, are frequently taken by the device
termed a decoy, which, in the low parts of Essex, and some other marshy districts, may be considered
as connected with husbandry. A decoy is a canal or ditch, proportionally pipe of water (fig. 940), with a grassy

sloping margin (1) at its junction with a river or larger piece of water (5), to invite aquatic fowls to sit on
and dress their plumage; but in other parts, covered with rushes and aquatic plants for concealment.
Along the canal of the decoy are placed reed fences (2, 2, to conceal the decoy man and his dogs from the
sight of the ducks. There is an opening in this fence (3), where the decoy-man first shows himself to the
birds to force them to take the water; and having taken it, the dog drives them up the canal, the man
looking through the fence at different places (4, 5, 6) to frighten them forward. At the end of the canal is a tunnel net (7), where the birds are finally taken. In operating with this trap, as the wild duck is a very skilful swimmer and delights in deep water, the first step is to make the water a peaceful asylum, by suffering the ducks to rest on it undisturbed. The same love of concealment leads them to be partial to waters whose margins abound with underwood and aquatic plants; hence, if the given water is not already furnished with these appendages, they must be provided; for it is not retirement alone which attracts the ducks, but a season of the year, when wild fowl are off their feed, they are equally delighted with a smooth grassy margin, to adjust and obstruct themselves upon. On the close-posted margins of large waters, frequented by wild fowl, hundreds may be seen amusing themselves in this manner, in the same way as the snare is placed by the canal to hide the decoy-man as well as his dog, until the signal be given. On reaching the head of the ducks, the decoy-man drives the water; where the wild fowl consider themselves as safe from the enemy which has assailed them, and of course do not take wing. Another use of the wild fowl, a parcel (perhaps eight or ten) of decoy-ducks should be mixed, which will probably be instrumental in bringing them, with greater confidence, to the bank. As soon as these are in the water, they make for the decoy, at the head of which they have been constantly fed, and in which they have always found an asylum from the dog. The wild ducks follow; while the dog keeps driving behind; and, by that means draws off their attention from their trap they are entering.

When, as soon as the decoy-man, who is all the while observing the operation through peep-holes in the reed screen, sees the entire shoal under a canopy net which covers and encloses the upper part of the canal, he shows himself, when the wild fowl instantly take wing, but their wings meeting with an imperious net, instead of a natural canopy, formed of reeds and bulrushes, their motion is checked, and the man being afraid to recede, the man being close behind them, they push forward into the tail of the tunnel net, which terminates the decoy. In this way, nine dozen have been caught at a time.

The soil of the country contains a natural larva, preserving for a natural inlet or creek of the principal water. The mouth ought to be spacious, and free from confinements, that the wild fowl, on their first rushing into the water, and while they have yet the power of recollection, may be induced to follow the same path. The same purpose it ought to be crooked, that its inward narrowness, and the nets, may not, in the first instance, be perceived. It is near the part of a canal, the bank of which is considered as the best form of the canal of a decoy that can be had. A material circumstance remains yet to be explained. It is to be observed that wild fowl take wing with their heads towards the water, and it is always advantageous to place them in a decoy from which they take wing, the opposite way. For, while their enemy is to leeward of them, they have less scruple to go up the pipe, making sure of an escape by their wings. But, what is of still more consequence, if the wind set up the pipe when they take wing under the canopy net, some of them may be purposely escape, and the circumstances always to be dreaded, and those which fell again into the water would, of course, with their heads towards the bank, would with greater difficulty be driven into the tunnel. This point is so well known by decoy-men in general, that every decoy is, in which circumstances will admit of it, furnished with three or four different canals, pointing to distant quarters of the horizon, that no opportunity may be lost on account of the wind being in any particular point.

7511. The goose (Aves Anser L., fig. 941.) is a native of Britain, and most parts of the north of Europe, but less common than the duck.

7512. The flesh of the common and various species of geese is highly stimulant, strong in flavour, viscous, and of a putrescent tendency. The flesh of the tame goose is more tender than that of the general, that every decoy will, to a feather, exactly suit for making soup; but in the tame kinds, no two of any species are exactly alike; different in their size, their colours, and frequency in their general form, they seem the mere creatures of art; and having been so long dependent upon man, have for the most part been entirely suited to culinary necessities.

7513. There is a Chinese species (A. cygnædes), and an American goose (A. canadensis). The Chinese species is a domestic bird, but as yet little known in this country. It is longer and narrower in the body than the common goose, and stands higher on the legs. The Canadian goose is domesticated in several places, and is not considered uncomely in the field. It is the most common of the goose kind on water in pleasure-gardens, and is abundant in the Duke of Devonshire's park at Chiswick.

7515. Breeding. One gander is generally put to five geese; the goslings raise from fifteen to twenty eggs; and the goslings are taken up in thirty days, or rather sooner. The goslings are fed by the female begins to carry straw in her bill, and by other means declares her readiness to take food. This generally in March, and sometimes two broods are produced within the season; an advantage obtainable by the warm water of the ground, and on the commencement of the breeding season allowing them boiled barley, malt, fresh grains, and fine pollard mixed with ale or other grain; ye good gander sits near his goose whilst they are sitting, and vigilantly protects them. Feeding upon the nest is seldom required; and it is unnecessary to take any of the goslings from the mother as hatched; but pen the goose and her breed at once upon the grass well sheltered, putting some grass between the mother and the young, allowing, or not at all in severe weather, and ever taking them in early in the evening. The first food may be

8 A 3
their range: and he says he has known them killed by swallowing sprigs of yew. As the young become pretty well feathered, they become also too large to be brooded beneath the mother's wing, and hence they do then sleep in groups by her side, they must be well supplied with straw beds, which they will convert into excellent dung. Being able, says Mowbray, to frequent the pond and range the common at large, the young geese will obtain their living, and few people, favourably situated, will allow them any thing more, excepting the vegetable produce of the garden. But it has been a constant practice always to dispense a moderate quantity of any solid corn or pulse at hand to the flocks of store geese, both morning and evening, on their going out and their return, together, in the evening more especially, with such greens as chanced to be at command: cabbage, mangel-wurzel leaves, &c., are most esteemed. With clean and dry such full keeping his geese were ever in a fleshy state, and attained a large size; the young ones were also forward and valuable breeding stock. Geese managed on the above mode will be speedily fattened green, that is, at a month or six weeks old, and after the run of the latter must be sufficient to make them thoroughly fat. A goose fattened entirely on the stubbles is to be preferred to any other; since an over-fattened goose is too much in the oil-cake and grease-tub style, to admit even the ideas of delicacy, tender firmness, or true flavour; but when needful to fatten them, the feeding-houses already recommended for hens (7517.) are most concert. With clean and renewed beds of straw, plenty of clean water, oats, crushed or otherwise, pea or bean meal (the latter, however, coarse and ordinary food), or pollard mixed up with skim-milk, geese will fatten pleasantly and speedily.

7517. Feathers. Pennant, in describing the methods used in Lincolnshire in managing geese, says, "They are plucked five times in the year; first at Lady-day for the feathers and quills, and four times for the feathers only, between that and Michaelmas." He says, he saw the operation performed on goslings of six weeks old, from which the feathers of the tails were plucked, and that numbers die of the operation if the weather immediately afterwards proves cold. This seems a cruel practice, and surely would be better left off. Lean geese furnish the greatest quantity of down and feathers, and of the best quality.

7518. The mute or tame swan (Cygnus cygnus L., fig. 942.) has long been known in England, but is only found wild in Russia and Siberia. It has been preserved by the severity of the laws, which have long accounted it felony to steal their eggs. Formerly they were fattened at Norwich for the city feast, and commanded a guinea each. The foot of the swan possesses nearly the same property as that of the goose; and the skin was formerly held to contain medical properties. At present swans are chiefly to be considered as ornamental in pleasure-gounds, clearing water from weeds, and occasionally affording cygnet and some swan down feathers and quills. It is a curious circumstance that the ancients considered the swan as a high delicacy, and abstained from the flesh of the goose as impure and indigestible.

7519. Other species are, first, the swan goose (A. cygnoides L.). This is of an intermediate size between the same tame and the common goose, with the last of which the wild is not easily confounded; and although they vary considerably in their colours, the species is always known by a knob on the tail. The two others which have been domesticated with us are the Canadian and the Egyptian species. The first is equally valuable with the common goose, and is very ornamental in ponds; the latter is now become very rare. The black swan, once considered a prodigy, is abundant in various parts of New Holland or Australia.

7520. Beak. The swan feeds like the goose, and has the same familiarity with its keepers, kindly and eagerly receiving bread which is offered, although it is a bird of courage equal to its apparent pride, and both the cock and hen are extremely dangerous to approach, and still more to incite to action, or whilst their brood is young, as they have sufficient muscular force to break a man's arm with a stroke of their wing. They both labour hard in forming a nest of water plants, long grass, and sticks, generally in some retired part or inlet of the bank of the stream or piece of water on which they are kept. The hen begins to lay in February, producing an egg every other day until she has deposited eight, or perhaps even nine, in these three weeks, although Button says it is nearly two months before the young are excluded. Swans' eggs are much larger than those of a goose, white, and with a hard and sometimes tuberous shell. The cygnets are ash-coloured when they first quit the shell, and for some weeks after; indeed, they are but change their colour, nor begin to moult their plumage, until twelve months old, nor assume their perfect glossy whiteness until advanced in their second year.

7521. Feathers and down. Where the living swan is plucked, only the ripe down should be taken from each wing, and four or five feathers. This may be repeated to the extent of three times in the course of a summer.

7522. The bustard (Ovis tarda L., fig. 942.) is a native of England, the largest indigenous land bird in Europe, the cock generally weighing from twenty-five to twenty-seven pounds. The neck a foot long; the legs a foot and a half. It flies with some little difficulty. The head and neck of the cock ash-coloured; the back barred transversely with black and bright rust colour. The greater quill feathers black, the belly white; the tail, consisting of twenty feathers, marked with broad black bars: it has three thick toes before, and none behind.

7523. Three species of bustard are found in England; that called the little bustard (O. latra) differs chiefly in size, not being larger than a small goose. Bustards, and occasionally several bustards, are supposed to live about fifteen years; areregarious, and pair in spring, laying only two eggs, nearly of the size of a goose egg, of a pale light brown, marked with spots of a darker hue. They sit about five weeks, and the young ones run, like partridges, as soon as deliv- ered from the shell. The cocks fight until one is killed or falls. Their flesh has ever been held most delicious; they are
fed upon the same food as the turkey. There were formerly great flocks of bustards in this country upon the waste lands in the wolds, particularly in Norfolk, Cambridgeshire, and Dorset, and in various parts of Scotland, where they were hunted with greyhounds, and were easily taken. Buffon was mistaken in his supposition that these birds are incapable of being propagated in the domestic state, chiefly on account of the difficulty of obtaining proper food, which, in their wild state, he describes to be heath-berries and large earth-worms. Probably the hawk or whitethorn berry might succeed equally well. To those who aim at variety and novelty in this line, the bustard appears peculiarly an object for propagation and increase, since the flesh is of unrivalled excellence; and it is probable this fowl will render greater weight of flesh for the food consumed.

**Sect. IV. Diseases of Poultry.**

7524. The diseases of poultry are generally the result of improper nourishment and lodging, and the best mode of cure is by the immediate adoption of such as is proper. When that will not succeed, very little help can be derived from medical assistance; at least as that art stands at present with respect to poultry. In fact, as Mowbray observes, the far greater part of that grave and plausible account of diseases to be found in our common cattle and poultry books is a farago of absurdity, the chief ground of which is random and ignorant guess-work.

7525. Common foods are attacked by the pip, roux or catarrh, the flux, constipation, and vermin. The pip is an outside skin or scale, growing on the tip of the tongue, and is cured by tearing off the skin with the nail and rubbing the tongue with salt. Imposheme on the rump is called the roux, which term is also applied to catarrh, to which gallinaceous fowls are very subject. The impostheme is to be opened, the core thrust out, and the part washed with salt and water. Generous food and warmth is the only cure in the catarrh. The flux is to be cured with good solid food; and if it be accompanied with scalded brain mixed with skin-milk of owls, adding a small quantity of sulphur. Vermin appear in consequence of low keep and want of cleanliness; the simplest remedy is to allow plenty of sand and ashes for the birds to roll in, and to keep their houses and roosts sweet and clean, white-washing them two or three times a year.

7526. The roux is a very common, and one of the most fatal, complaints to which chickens are subject. Those attacked by the disease are constantly coughing and gasping for breath. Upon dissection the wind-pipe is found almost closed up by great numbers of small red worms, which, in a certain stage of their growth, congregate into bundles large enough to stop respiration, and which, if the sufferer cannot discharge at the mouth, soon produces suffocation. Decotions of the common yellow Linaria vulgaris (Hort. Brit. L. 1845) is given as drink, which, being nauseously bitter, is supposed offensive to the worms; but perhaps some mercurial preparation, taken inwardly, would answer the purpose, and, if effectual, would save thousands of chickens every year. This suggestion has never been tried.

7527. But the catarrh is the chief disease to which chickens and fowls are liable; and when the malady becomes confirmed with running at the nostrils, swollen eyes, &c., they are termed roupy, the suffix thus being infectious. They should now be separated, and kept in a warm apartment and well fed. Roupy hens seldom lay, and their eggs are unwholesome. In chickens this disease is called the chip; they are seen shivering, pining, and dying in corners, apparently from cold, though they are in fact in a fever. Abundant warmth and rich food are the only remedies.

7528. Broken legs, wings, or toes may be set and spliced, and will recover: the head being raw and the eyes blinded from fighting, wash the eyes with milk and water, and the head alternately with brandy in which is a few drops of laudanum, and with fresh butter. A cock's spurs being too long, impeding his walk and wounding his legs, they should be cut carefully with a sharp pen-knife, but not too near the quick, every three months.

7529. Grease are subject to the gargle, or stoppage in the head, the consequence of cold. House the patient, and give garlic beer up with fresh butter; or toast and ale, with a little confinement, will succeed equally well.

7530. All poultry, when young, are apt to be carried off by rats and other vermin, which must either be vigilantly guarded against or destroyed.

**Sect. V. Birds of Luxury which are or may be cultivated by Farmers.**

7531. Birds of luxury include the pigeon, pheasant, partridge, quail, grouse, singing birds, and birds kept as curios objects.

7532. Of the pigeon (Colymba L.) there are three species and many varieties in cultivation. The species are the common, ring, and turtle doves, all natives of Britain. The varieties of the common pigeon enumerated by Linnaeus amount to twenty-one; but those of the pigeon-fanciers to more than double that number. The ring-dove (C. Palumbus L.) and the turtle-dove (C. Turtur), with the greater number of the varieties, are cultivated only by a few persons, known as pigeon-fanciers; but the common pigeon of different colours is cultivated for the table.

7533. The flesh of the young pigeon is very savoury and stimulating, and highly valued for pies; that of the full-aged pigeon is more sublimated, more tender of digestion, and in a considerable degree heating. Black or dark feathered pigeons are dark fleshed and of high flavour, inclining to the game-bitter of the wild pigeon. Light-coloured feathers denote light and delicate flesh. The dung of pigeons is used for tanning upper leather shoes for horses; it is also an excellent manure. Pigeons are now much less cultivated than for mops, bakers, and injurious to corn fields, and especially to fields of peas; they are, however, very ornamental. A few may be kept by most farmers, and fed with the common poultry; and some who breed domestic fowls on a large scale may, perhaps, find it worth while to add the pigeon to their number.

7534. The variety of pigeon most suitable for the common pigeon-house is the grey pigeon (fig. 941), inclining to ash-colour and black, which generally shows fruitfulness by the redness of the eyes and feet, and by the ring of gold colour which is about the neck.

7535. The varieties of the fancy breeders are numerous, and distinguished by a variety of different names, as carricks (fig. 945. a), carparks, partridges, horsemens, runts, jacks, jackdaws, turkeys, helmets, nutcrackers, 941. b, bars, petits, ovals, spoons, trumpets, shakers, turners, finksins, &c. From these, when differently paired, are bred bastard pigeons; thus from the crane or power and the carrier is bred the pouting horsemens (c); from the tumbler and the horsemens dragoons, &c.
7556. The stacking of pigeon-houses is best performed in May or August, as the birds are then in the best condition. Young birds called squeakers should be chosen, as the old are apt to fly away.

915

7557. In breeding, the pigeon lays two white eggs, which produce young ones of different sexes. When the eggs are laid, the female sits fifteen days, not including the three days she is employed in laying, and is relieved at intervals by the male. The turns are generally pretty regular. The female usually sits from about five in the evening till nine the next morning; at which time the male takes her place, while she is seeking refreshment abroad. Thus they sit alternately till the young are hatched. If the female does not return at the expected time, the male seeks her, and drives her to the nest; and should he be in turn neglected, she retaliates with equal severity. When the young ones are hatched, they are fed for the first three days; a task which the female takes entirely upon herself, and never leaves them except for a few minutes to take a little food. After this they are fed about ten days, with what the old ones have picked up in the fields, and kept treasured in their crops, from whence they satisfy themselves, who receive it very greedily. This way of supplying the young with food from the crop of the pigeon-kind, differs from all others. The pigeon has the largest crop of any bird, for its size; which is also quite peculiar to the kind. In two that were dissected by an eminent anatomist, it was found that, upon blowing the air into the windpipe, it distended the crop or ventriculus, and caused a sort of turgidness in the pigeon's crop, to the tendering of its young ones. Its feathers, mixed together in the crop are digested in proportion as the bird lays in its provision. Young pigeons are very ravenous, which necessitates the old ones to lay in a more plentiful supply than ordinary, and to give it a sort of bulk to the crop, to tender it for their young ones. The numerous glands, assisted by air and the heat of the bird's body, are the necessary apparatus for secreting a sort of pap, or milky fluid (commonly called pigeon's milk); but as the food digests, it also swells, and the crop is considerably dilated, are now days filled with solid substances, the bird could not contract it; but it is obvious the bird has the power to compress its crop, and to force the aliment into the crop, which is forced up into the gullet with great ease. The young usually receive this tribute of affection from the crop three times a day. The male for the most part feeds the young female, and the old female performs this service for the male. While this provision is being digested, and its nourishing matter is absorbed by the veins, the crop is filled with new aliment; and when it is thus engorged, the bird from time to time, has a sort of rumbling, which is heard in the air, and the crop is emptied into the gullet by the ducts of the crop, which is somewhat in the open air, and water should be given internally. That this may be done without waste, and without frequently distributing ; as it is difficult to provide, the following and two contrivances are in use: the first is the meat-box, or hopper, from whence grain or pulse descends from the hopper as eaten out of a small shallow box ; three of the square for hens, and one of the square for doves. And in order to hinder rats from climbing up the outside of it, the wall should be covered with tin-plates to a
certain height, as about a foot and a half; which should project out three or four inches at the top, to prevent their getting up more effectually. As the sides are of wood, it is to be boarded on a strong post, powerfully braced (fig. 943), the interior sides of which are lined with boxes for the birds (a), and the external east and west sides with balconies, or sills for them to alight on, and on their boxes (b). The north and south sides are lined with boxes inside, but without openings, as being too cold on the one front, and too warm on the other.

The interior of the pigeon-house must be lined with nests or holes; subdivided either by stone, as in the ancient mural pigeon-houses; by boards; or each nest composed of a vase or vessel of earthenware fixed on its side. Horizontal shelves (fig. 947), divided very boldly, three feet distance, are generally esteemed preferable to every other mode; the width of the shelf may be twenty inches, the height between shelf and shelf eighteen inches; and a shelf of board three or four inches high is carried along the front of the partitions to keep in the nests. Sometimes, also, a partition of similar height is fixed in the middle of each three-feet division, which thus divides it into two nests. This Mowbray and Girton concur in recommending, as likely to prevent injury from running to the hen when sitting over fresh eggs, and perhaps occasioning her to cool and abide them; for when the young are about a fortnight or three weeks old, they will go to the care of the cock, and lay again. Some prefer breeding-holes with no board in front, for the greater convenience of cleaning the nests; but as the squab is apt to fall out of this practice, a good way would be to contrive the board in front to slip up and down in a groove, by which each nest might be cleaned at pleasure. As tame pigeons seldom take the trouble of making their own nest, it is better to give them one of hay, to prevent the eggs from rolling. There are also straw buckets made in the form of nests, and also nests or pans of earthenware. Where pans are used, it is common to place a brick between them (two being placed in a breeding-hole), for the cock and hen to alight on; but on the whole straw is better. The pigeon-house has two entrances, one a common-sized door for man, either on the ground, a step, as used formerly to the case, and the other on a rising above the roof, and consisting of small holes three or four by twelve or fourteen inches, for the entrance of the pigeons. A series of ranges of these are generally placed over each other, in a boarded front looking to the south, with a shelf to each range, and surrounded by a row of windows to protect them from cats.

The elevation of pigeon-houses (fig. 945) as already described, are of endless variety.

7543. The breeding holes constitute the fixtures of the pigeon-house; its utensils are the hopper and bottle already described (7539), a barrel or box for food, a ladder or step to reach the upper storey and some other articles not peculiar to this department of rural economy. The pigeon-trap, for enticing and entrapping the pigeons of others, we do not describe.

7544. Diseases of pigeons. Fancy pigeons, being many of them monstrosities, productions, are very subject to diseases. Girton enumerates upwards of a dozen, with their cures, including the corruption of the egg in the uterus from over high feeding; a gorged crop; dysentery; bronchitis; jaundice, and other ailments not peculiar to this department of rural economy. The pigeon-trap, for enticing and entrapping the pigeons of others, we do not describe.

7545. Pigeons in new lodgings are apt sometimes to forsake their habitations. Many nostrums have been recommended to prevent them from doing so; but if squabs be selected, cleanliness and security attended to, and a salt cot placed in or near the house, there will be little danger of this taking place. Fumigation with highly odoriferous drugs, or even assafotida, is also said to attract pigeons to a neglected dovecote, or attach them to a new one.

7546. Laws respecting pigeons. By the 1st of James, c. xxvii., shooting, or destroying pigeons by other means, on the evidence of two witnesses, is punishable by a fine of 20s. for every bird killed or taken; and by the 2d of Geo. III. c. xxix. the same offence may be proved by one witness, and the fine is 20s. to the prosecutor. A lord of the manor or freetholder may build a pigeon-house upon his own land, but a tenant cannot do it without the lord's licence. Shooting or killing within a certain distance of the pigeon-house, renders the person liable to pay a forfeiture.

7547. The common pheasant (Phasianus colchicus L.) is a native of the old continent, but not of America, and has long been naturalised in the warmer and most woody counties of England. It is very common in France, and before the Revolution used to be a great nuisance to the farmers, even to the gates of Paris. The pheasant runs fast, but flies low and heavily; it crows not unlike the common cock, being of the same genus, and is supposed to live six or eight years.

7548. Pheasants are both granivorous and carnivorous; they feed upon all sorts of insects and vermin like the peacock, and are said to be greedy of toads, when not too large to swallow them; when ducks, according to report, they do not touch the frog, of which ducks are so fond. They are prized in park scenery for their beautiful plumage and showy figure, and as game for the delicacy of their flesh, which is of a high flavour and alkalescent quality. It is in season both in summer and autumn, and esteemed when under a year old, and very fat. Every gentleman who has a well wooded, well timbered estate, and in walled parks or woods, may stock it with pheasants; and he may preserve his stock if he will continue to supply them with abundance of food, and destroy thieves, peacocks, &c. &c. The more common the pheasant becomes, the less will it be subjected to the attacks of those enemies.
PRACTICE and good breeders. The ring-ants, natives of Tatar, bred in China, very scarce; their plumage very beautiful. The white and pied; both sorts will intermix readily with our common breed, as will the Bohemia, one of the most beautiful of its kind, and equally scarce. The golden variety is generally of the breed.
7556. **The partridge (Tétrao Pérduix, fig. 949.)** is a native of all the temperate regions of Europe, but unable to sustain rigorous cold or intense heat.

7557. Partridges are highly valued as food on most parts of the Continent, and as a table luxury in England. In the Ukraine both partridges and pheasants are more abundant than anywhere else in Europe; they were formerly so common in France, that Rozier informs us that the cul-
tivators were obliged to sow three or four times the corn that was necessary to raise a crop, and that even this had often to be done three or four times in a season. The bird feeds like the pheasant on insects and seeds, and is par-
ticularly fond of those of the wild mustard. It has not been domesticated, but may be hatched and reared in the same manner as the pheasant.

7558. **The quail (Tétrao Coturnix, fig. 950.)** is a native of the East, and abounds in Egypt, as appears from the supplies the Israelites obtained while in the wilderness, and also in the islands of the Archi-
pelago, and in Italy. They migrate from warmer to colder regions. They are naturalised and breed in England, chang-
ing their residence within it on the approach of winter, from the more exposed to the more temperate districts. They are very abundant in France, and are caught in snares and nets of England, Wales, and Scotland, and sent both to the Paris and London markets. The bird was proverbial among the Romans as captious and quarrel-
some, and is employed among the Chinese for the same amusement as game cocks are in England. Here it is not domesticated, but may be reared and preserved in the same manner as the pheasant and partridge, and its food is nearly the same as that of the latter bird.

7559. **The red grouse, or moor cock. (Tétrao scoticus, fig. 951.)** is an esteemed variety of Gallinacea, pursued with avidity by sport-men in the mountainous districts into two crooked expansions, among the grouse from intestinal worms.

7561. **The wood grouse, or cock of the wood (Tétrao Urogallus, fig. 953.),** is, after the bustard, the largest bird among those we call game; it being little less than a turkey. It was originally com-
mon in the mountainous parts of Britain; but is now nearly if not wholly extinct with us; though still com-
mon in the northern parts of Europe, where it lives in pine forests, on the cones of which it is supposed to sus-
bit, and which at some seasons gives its flesh a terebin-
thinatated taste: at other times it is delicious eating, and is often sent to England frozen. Like the other grouse, he has the scarlet patch on his head, his legs are defended in the same manner by a feathered covering, and his whole markings are equally varied and beautiful. From the richness of the plumage in all the varieties of the Tétrao, and from the extreme delicacy of their flesh as an article of food, it is to be lamented that attempts are not made to domesticate them in addition to our other poultry. It is thought by observant sportsmen and scientific naturalists, that this might be attended with less difficulty than the domesticating the partridge and pheasant; and the attempt is recommended to the patriotic amateur.

7562. **The lark (Alauda arvensis L.)** and other birds were reared and fattened by the Romans for the table. The lark is caught by nets and other means in some of the open districts of England, as about Dunstable, Cambridge, &c., and brought to market for the table, as are various other birds by a particular class of men known as bird-catchers. It is an idle uncertain kind of life not to be recommended.
7563. Of singing birds, a great variety are domesticated; and their breeding and rearing forms a very peculiar and curious branch of rural economy. Not only all the birds which please by the natural song are domesticated and kept in cages, as the canary, nightingale, lark, linnet, finch, thrush, &c.; but even some which do not sing in a wild state, as the sparrow, hammer, &c., are by art taught the notes of other birds.

7564. Wild singing birds are caught by various devices, according to the species of bird and season of the year. The pairing season in spring, generally March and April, is on the whole the best season, and the common means are a net called a clap-trap; a bird of the species to be caught, called a call-bird, to attract the bird; and another, a female bird. Call-bird is also very generally used; and for nightingales, a small hole dug in the ground covered with a perforated board, or a small round spring trap, called a nightingale trap, is resorted to. Glasses called larkers are used to call larks, and hawks are used to frighten some species, to render them more readily taken. As it is only the male birds which sing, or at least are of any value for their song, it is a very material part of the bird fancier's art to know the male from the female when they are both young; in general he is larger and longer.

7565. In breeding and rearing tame birds the chief art consists in teaching them to sing. This is frequently done by the human voice alone, but more commonly by the aid of the flageolet or a small barrel organ. The organ is used in Germany in teaching the nightingale-notes to the canary, and in teaching regular tunes, as marches, waltzes, &c. to the bullfinch, which after being so taught are called piping bullfinches, and oat from 5l. to 7 or 8 guineas each in London. In Italy the canary is taught various notes and tunes by the flageolet. In France, and also in this country, one bird is taught by another being placed in a cage near it. When not taught at all, and not within the hearing of other birds, each bird utters its natural notes but very imperfectly. In general they are more ready to imitate the note of any bird they hear, even of a hen or duck, than to utter those which are natural to the species. This certainly appears singular, but it is a well known fact.

7566. The aviary, or place for breeding and keeping singing birds, may be a long narrow apartment fronting the south; the front to be covered with wire netting, and within this glass sashes, which may be removed in summer. There should also be a flue in the floor or back wall to supply heat in cold weather. In such a building various birds may be kept in cages, or a few sorts in compartments. Thus a considerable space may be allotted to the breeding of the canary, for which there is the greatest demand; the next singing birds are invariably found to sing best when kept in separate cages, and apart from each other. In gardens or pleasure-grounds these cages may be suspended from trees, or supported by light iron props (figs. 954, 955); and those who would wish to pursue this branch, either as one of amusement or profit, will find ample instructions in Thomson's Bird Fancier, and other similar works.

7567. Foreign aquatic birds may be kept in the artificial waters of pleasure-grounds by shortening the feathers of one wing, and without any other care than a duck-house or shelter during night.

7568. The training of hawks and other birds for hunting, of decoy birds of different sorts, as ducks, singing birds, pigeons, &c., belongs more to sportmanship than agriculture, and may be learned in Daniel's Rural Sports, and various old books, such as The Country Gentleman's Recreation, &c.

**CHAP. X.**

Fish and Amphibious Animals subjected to Cultivation.

7569. The cultivation of fish is carried on to a very limited extent in Britain, owing to the great superiority of the sorts obtained by fishing in rivers or the sea, and to the decline of the catholic religion, which no longer renders fish an article of importance on certain days and seasons. However, in a few places fish are bred and reared for the market, and in gentlemen's grounds in the interior of the country some attention is generally paid to stocking the ornamental pieces of water with appropriate fish. Bakewell, in his instructive Travels in the Tarantaise, suggests the idea of introducing exotic fish and naturalising them in our lakes and rivers, and he mentions some Swiss species that he thinks would be particularly valuable. In the Edinburgh Review for 1822, is a curious paper on the possibility of rearing sea-fish in our fresh water lakes. See also Brande's Quarterly Journal, Nos. xxxiii. and xxxiv. It appears that the founder and the mullet have been naturalised to fresh water; and that it is probable the whole of the fishes of analogous habits, and particularly those of the genus Pleuronectes, might be habituated to inland lakes.

7570. The mode of constructing ponds for retaining water for general purposes has been already described (4467.) Ponds, expressly for the purpose of breeding and rearing fish, are formed at least expense in deep valleys, and slight depressions between hills, where there are rivers or waters; and
different ones may often be made on the same line, the head of one constituting the bottom of that above it. The extent of them must be regulated by the nature of the situation, and the supplies or water that can be procured. In situations of this nature, the principal expense consists in constructing the banks or heads across the valleys, for keeping up the waters, and providing them with suitable shutes, which, where the land is of the heavy clay kind, may be completely ironed in the manner that earth works are usually performed. The foundations being laid sufficiently deep, and the earthy materials well applied by proper paddling and ramming, in the way of making embankments. The heights and strength of the dams or heads will be governed by the situations, and the quantity of water required to be kept up.

The slopes should be the greatest which are next the waters. There must also be diverting channels for taking off the superabundant waters in the time of floods, which may be formed along the sides; the shutes being placed in the lowest parts, and being well made of seasoned oak, and tightly rammed in with the earthy materials. Detailed instructions on this subject will be found in the Quarterly Journal of Agriculture, vol. i. p. 287.

751. Sea water fish ponds are unknown on the Continent, and not common in England. In Scotland, however, a fish pond is said to be formed by a hollow, which is butts and ditches, filled with water from the sea, and the sides and bottom are usually kept clear of grass and other plants by burning or hoeing. Marble Rock, in the north of the county of Aberdeen, may be mentioned as a place where a fish pond is said to have been formed by sea water for carrying fish without the expense of a channel or sluice. The walls of the trough are a foot or more in thickness, and are carried up two feet or more, into the sides of the pond. The water is kept up by a fall of about two feet. The pond is divided into three parts by two pieces of wood, and has the appearance of a fishpond. The plants which are to be expected here are common to the sea and fresh waters.

752. The kinds of fish adapted for ponds are chiefly the carp, tench, perch, gudgeon, eel, and pike.

753. The carp (Cyprinus Carpio L. fig. 955 a) is by far the best fish for artificial management, and especially that variety known in England as the Prussian carp. Carp inhabits the slow and stagnant waters for Europe; old Persia, and was introduced into Britain in the year 1514; about four feet long; greatest and is very long; lives on herbs, fat earth worms, and aquatic insects, and any soft substance; is extremely fertile, and the young fish, as the spawn, can be obtained for food; aquatic birds, and frogs; body above blue-green, the upper part of the sides greenish-yellow, and blackish, beneath white; tail yellow; scales large, long; body subangular; tail fin. Of the gall that is made a green paint, and of the sounds or air-bladder a fish-glide.

754. In raising carp, it is often the practice to have three ponds:—One for the purpose of spawning the fish in, and in which they should be left during the rest of the summer and the following winter, as they mostly spawn from the beginning of May to the latter part of July; another for the convenience of nursing up the young fry, and lastly, or pur the latter end of March or April, choose a calm but not sunny day for the business; after which they should be carefully preserved from coming to the sides and being destroyed: in this pond they may remain two years, and become three, five, or six inches in length, and good for use. Simultaneously with or for more than two years, is destined for the events of the pond, and for which the sides are to be stocked with these:—For each acre of the first, "three or four male carps, and six or eight female ones;" the most suitable sort for this use being "those of five, six, or seven years old, in good health, with full scale, fine full eyes, and a long body, without any blemish or wound." The ponds should be previously cleared of all sorts of voracious fishes and other animals, as "perch, pike, eel, and trout; the water-beetle, and also the newts or lizards." Such ponds as are warm and have an open exposure, with soft water, are the most proper for the carp. For making ponds, a thousand or twelve hundred may not be more than sufficient for an acre; and for the main ponds, one to every square of fifteen feet is the proportion advised, as their growth depends greatly on the room and quantity of food that is allowed. The best seasons for performing the business in this case are those of the spring and autumn. In summer, the young, in order to preserve their strength, should be put into the water just before the winter, under the ice; feeds on worms and water plants that is to be daly, body covered with a thick nuxucus, and small scales which adhere firmly to the skin; above dark-green, the sides above the line green, beneath yellow, yellow; varies in its colours by age, the sexes; for which the water it inhabits; flesh white, soft, and well tasted.

755. In stocking with tench the number per acre may be more than of carp. In Berkshire, where there are many ponds for the preserving of fish, they usually stock with tench or carp in the proportion of one hundred to the acre, the fish remaining four years in them; but in the management of Sir Harry Macdonnel, the tench is stocked in the proportion of twelve hundred and an equal number of tench; or at the rate of seventy-five brace to the acre. And in this proportion they are said to succeed well.

756. The gudgeon (Cyprinus Gilio L. c) is a very inferior fish to the carp or tench; but being of easy cultivation, is kept as a food for fish ponds. It inhabits gentle streams and lakes of Northern Europe; is tenacious of life, and very fertile; about eight inches long; feeds on herbs, worms, insects, the fry of other fish, and parts of carcasses: the body is somewhat thick, more or less doted; or spotted, or narrow, spotted or covered with a thick nuxucus, and small scales which adhere firmly to the skin; above dark-green, the sides above the line blue, beneath whitish yellow, but it varies its colours by age, the different waters it inhabits; flesh white, soft, and very delicate.

757. The perch (Perca fluviatilis L. d) is an excellent fish, and though naturally found in streams in Europe and Siberia, yet will live in large ponds or lakes, provided the water be clear. It grows to two feet long; back and part of the sides dark green, with live broad black bars, which are sometimes dark green or blue, and very rarely wanting; belly white, tinged with red; swims with great swiftness and at a great height above the water; is tenacious of life, but eagerly takes small objects; feeds on aquatic worms and young aquatics; is very prolific; it has no real air-bladder; and from its situation of its gills, may be obtained a kind of glue; flesh very delicate.

758. The pike (Esox lucius L. e) is a most voracious fish, large and very prolific; it has no real air-bladder; and from its situation of its gills, may be obtained a kind of glue; flesh very delicate.

759. In stocking with perch, as they are great breeders, six hundred to the acre may be sufficient.

760. In stockimg with eel, or they are to be made, the number of feet of which the pond is to be stocked will be about thirty, or even forty, the number of the feet or the eel. The eel is a very searching fish, and will feed on any manner of food, and is very prolific; it has no real air-bladder; and from its situation of its gills, may be obtained a kind of glue; flesh very delicate.

761. In stockimg with pike, they are very prolific; it has no real air-bladder; and from its situation of its gills, may be obtained a kind of glue; flesh very delicate.
for its food. It will thrive in wateres partaking of the chalybesitique quality, in which few other fish would live.

7581. The gold fish ( _Carassius auratus_ L.) is an inhabitant of the rivers of China and Japan, and is naturalised almost every where on account of its elegance and vivacity; the colours vary greatly, but are usually of a mottled red and gold or yellow, and it readily assumes any colour or hue, and is often grown in the gardens near London and Paris for sale, as an ornamental inhabitant of crystal vases, or garden basins of water.

7582. The minnow ( _Cyprinus Phoxinus_ L. 1.), the dace ( _C. lentiscus_ L.), and the roach ( _C. rutilus_ L.), are very small fish, which abound, the first in gravelly streams, and the others in still waters; both are useful as fooding for other fish, and may therefore be put into fish ponds. They are also very good for cat food.

7583. Of the trout and salmon family there are several species, as the lake trout, gill and red char, which inhabit Alpine lakes in northern countries, and might probably be introduced with advantage into the lakes of Cumberland, Westmoreland, and the Highlands of Scotland. The red char is caught in Kent, Cornwall, and the Lake district; and the salmon ( _Salmo salar_ ), or sea-trout ( _Salmo trutta_ ), a species of great magnificence, and the fresh water trout ( _S. fario_ ) requires too rapid a stream for art to imitate; they succeed, however, to a certain extent, in very slow running waters which are clear.

The young trout are particularly fit for propagation during the first year of their age. The roe of the female is found, on an average, to contain from 17,000 to 20,000 ova or eggs. During the months of August, September, and October, the reproductive organs, both of the male and female salmon, have more or less completely reached maturity, at which period the instinct of propagation impels them eagerly to seek rivers, and to ascend nearly to their sources, in order to find a place suitable for the deposition of their spawn. They no longer, as in the winter and spring months, roam over the coast and shores, and return backward and forwards with the flowing and ebbing of the tide; but pursue the most direct route by the mid-channel up the rivers, and make the greatest efforts to overcome every obstacle, either natural or artificial, that may impede their progress. The spawning is accomplished in the months of November, December, and January. When the parent fishes have reached their spawning ground, they proceed to the shallow water, generally in the morning, or at two or three hours after high water, when they round the bends, and then the male begins to make a murmur, by working up the gravel with their noses rather against the stream; as the salmon cannot work with his head down the stream, for the water then going into his gills the wrong way. When the female and male are made, the female takes one, and the other to the side of the fish. They then throw themselves upon their sides, again come together, and rubbing against each other, both shed their spawn into the furrow at the same time. This process is not completed at once; as the eggs of the roe must be excluded individually, from eight to ten pounds of overcrowded issues. In the operation, the opens the operculum to themselves to the pools to recruit themselves. The spawn thus deposited is afterwards covered with loose gravel; and in this state the ova remain for weeks, or sometimes much longer, apparently inert. Like some other fishes, it is not uncommon to find the fry come up in the spring, when the snows are melting, and the average temperature of the water is near 3° Fahr. Generally, they begin to rise from the bed about the beginning of March, and their first movement is generally completed by the middle of April. The appearance which they present is that of a thick brroid of gray or dark green, in vast numbers. The tail first comes up, and the young animals often leave the bed with a portion of the furrow along with the outside weight. When made upon the ova, it appears that they can only be hatched in fresh water; for when a portion of the roe was put into salt water, none of the ova ever came into life; and when a young fish that had been hatched in fresh water was put into salt water, it thrived for several hours. When the evolution from the ova is completed, the young fry keep at first in the eddy pools, till they gain strength, and then prepare to go down the river, remaining near its sides, and proceeding on their way, for months, and then they meet the salt water, when they disappear. The descent begins in the month of March, and continues through April and a part of May, and sometimes even till June. The reason why the fry thus descend by the margin in rivers, and the mid-channel in estuaries, is, apparently, according to Dr. Flemm., because the margin of the river is the easy water, and consequently best suited to their young and weak state; but when they reach the estuary or tide water, then the margin of the water being the most disturbed, the fry avoid it, and betake themselves to the deepest part of the channel, disapearing alake from observation and capture, and so go out to sea. After remaining some weeks at sea, the smelts or salmon fry are called, they are carried along the coasts and rivers, having obtained a pound or a pound and a half of weight; by the middle of June they weigh upwards of a pound, and increase half a pound in weight every week. They are now known in Scotland by the name of gilies, and by the end of the fishing season they have obtained the size of seven or eight pounds. In the first five months of the year, that is, from the middle of August to the middle of January, the salmon reaches, in favourable circumstances, eight pounds weight, and afterwards increases, though more slowly, so as to have acquired the weight of thirty-five pounds in thirty-three months. After the process of spawning is completed in the river, the adult or parent fishes retire to the adjoining pools to recruit. In two or three weeks from that time, the male begins to seek his wife, and the female begins to return again in autumn in breeding condition, a recovery which is no less remarkable than the early growth of these animals. The sea seems to be the element in which the salmon feeds and grows. When caught in fresh water, they are only in their condition comparatively poor, but scarcely any thing is ever found in their stomachs. In estuaries and on the coast, on the other hand, they are very fat and shalow, and their stomachs are often full of sand-eels. ( _Edin. New Phil. Jour. Jan.—April, 1828._)

9234. The perch ( _Muraena Anguilla_ L.) inhabits almost everywhere in fresh waters; grows sometimes to the length of six feet, and weighs up to five hundred pounds; in its spawning time it assumes a snakelike form; during the night quits its element, and wanders along meadows in search of snails and worms; beds itself deep in the mud in winter, and continues in a state of rest; is very impatient of cold, and is said to keep alive in the frozen lake; the flesh of the perch is very good; its frequent running water is very good; is vivisiparous, and has 116 vertebrae. One advantage of the eel is, that it will thrive in muddy ponds of very small size, where no other fish would live.

The subject of cultivating fishes it may be observed, that the waters of some ponds are better adapted for raising some sorts of fish than others. Thus, for example, the eel is much better adapted for carp than for this latter fish, for it requires a very large pond, which is managed by a spring, and there is a large portion of rich sediment. Pike should never be kept in ponds with carp, or other fish; for the same reason, which prevents the eel from breeding in the same pond. In some of our ponds, the supplies of small fry is considerable and not wanted for stores. Carp, tench, and dace should be kept with the sardine, or other fish, delighted with a view to profit, with a few eels occasionally. But perch and eels should not be admitted where the ponds are thus highly stocked; as they are great devourers of the young fish. Carp and tench answer best together where the extent of the ponds are pretty large; as, in other cases, the former, being from a much more powerful fish, beats and deprives the latter of his...
food. Carp seldom afford much profit in ponds of less extent than half an acre; but tench thrive well in those of almost every size, being often found good in ponds of only a few perchs square. Carp, perch, and eels succeed well together; and also tench and eels. Carp more frequently injure themselves by breeding than tench, though it sometimes happens with the latter. It is not improbable that in small fish ponds it might be the best practice to keep the carp and tench separate. The produce or profit afforded by fish-ponds has not yet, perhaps, been sufficiently attended to in different situations to afford correct conclusions; nor is it well ascertained what is the annual increase in different kinds, in different periods of their growth, and under different circumstances of soil and water. 

The taking of cuttivated fish is generally done with nets, and sometimes by emptying the pond of water. Whatever way is adopted, only those fit to be used are taken, and the rest returned to grow larger. No fish is taken with the fit to be used, for a month before and after the spawning season, and in fresh and salt water, by immersing a burning lamp in an air box with mirrors, and round which he has traps into which the animals are to be entangled, while approaching the light and the multiplied images of their own species. For this contrivance he has taken out a patent. Salmon are sometimes caught by torch-light.

The castration of fish has been successfully practised both in this and other countries, and both with the male and female. Castrated fish attain to a larger size, and are wintered together all the year. The mode of performing the operation is described in Reeve's Cyclopædia, art. Fish, Castration of, and in the Philosopohical Transactions, vol. 48. part ii. p. 166.

Of the amphibia which are or may be cultivated for food or ornament, the principal are the frog and tortoise.

The esculent frog (Rana esculenta L., fig. 957. a), though generally despised in this country, is yet an excellent article to those who are accustomed to it; and there are few Englishmen who have eaten a finerer of the thighs of this animal in France or Italy, than what I have tasted in this country. The body of this frog is green, with three yellow lines, the middle ones extending from the mouth to the anus, with the angles of the mouth turned in a globular form; the male makes a continual croaking in the evening, especially before rain; when irritated will pursue and destroy a pike. It is rare in England, but very common on the Continent, where it is in season for the table in June.

The tree frog (Rana arvalis L., b), is green above, and white beneath, with a yellow curved line on the side. In elegance and activity it is superior to every other European species. In summer it resides in the woods, and haunts the trees in quest of insects, which it approaches on its belly in the same manner as a cat to a mouse, and at length seizes with an elastic and instantaneous spring. It is particularly noisy on the approach of rain, and takes up its abode in the water a week before rain.

The common tortoise (Testudo graeca L., fig. 958. a) weighs three pounds, and is about seven inches. It abounds in the countries surrounding the Mediterranean, and particularly in Greece, where the inhabitants not only eat its flesh and eggs, but frequently swallow the warm blood. In September or October it conceals itself, remaining torpid till February, when it re-appears. In June it lays its eggs, in holes exposed to the full beams of the sun, by which they are matured. Tortoises attain most extraordinary longevity, and one was ascertained to have lived in the gardens of Lambeth to the age of nearly one hundred and twenty years. It will answer the purpose of a barometer, and uniformly indicates the fall of rain before night, when it takes its food with great rapidity, and walks with a sort of mewing and clack step. It appears to dislike rain with extreme aversion, and is discomfited and driven back only by a few and scarcely perceptible drops.

The mud tortoise (T. lutaria, b) is common both in Europe and Asia, and particularly in France, where it is much used for food. It is seven inches long; lays its eggs on the ground, though an aquatic animal, walks quicker than the land tortoise; and is often kept in gardens, to clear them from snails and various wingless insect. In fish ponds it is very destructive, biting the fishes, and, when they are exhausted by the loss of blood, dragging them to the bottom and devouring them. The tortoise may be fed on any vegetable refuse, milk, worms, offal, or almost anything. Linnaeus says they are in all things extremely slow, and in copulation profusely adhere together a month, and live several days after the head is cut off. (Shaw's Zoology.)
Insects and Worms which are or may be subjected to Culture.

7594. The silkworm and the honey-bee are the two most valuable insects in Europe. The first, from its great importance, has recently engaged the attention of the legislature, no less than of private individuals, who have embarked large sums in the attempts now making to introduce its culture in this country on a large scale. 7595. The silkworm is the larva or caterpillar of a moth (Bombyx mori, fig. 959:).

it is a native of China, and was introduced into Europe A.D. 160. When full grown the worm is nearly three inches long, of a yellowish grey colour, with a horn-like process on the last joint of the body.

7596. In Italy and other silk countries the eggs are carefully preserved in some place of cool and even temperature, where they remain until the new leaves of the white mulberry, which is its natural food, are produced. The object is to have the eggs precisely at this time, that the new born worm may be fed on food suitable to its infant state. A grower of silk never hatches his whole stock of eggs at once, as a night's frost will frequently destroy the leaves. Lettuce answers well in this stage of the worm's existence; but if it is fed entirely upon this plant the silk is of a very inferior description, and is, indeed, perhaps the most injurious food. The paler the green of the white mulberry, in fact, is superior in nutritious matter to that of all others. The leaves in the autumn succeeding to those stripped in the spring, are commonly given to cattle and pigs, who fatten upon them exceedingly. There is an unfounded prejudice in many silk countries that the silk produced from the second leaf is inferior to the spring crop, and in France and Italy the vernal leaf only is used. In India the mulberry tree is grown in moist places, like the osier in England, and produces from three to six crops annually; the prejudice therefore of the Italian and French growers against the second crop is unfounded. The real fact seems to be, that the worms are more difficult to breed in autumn than in spring, from the great change of temperature, against which the growers in general make no artificial provision. Another reason may probably be, that the silk is reeled with greater economy and advantage in the height of summer, when the length of the days, and the heat of the weather, is then sufficient to dry the thread in this operation. The native reeler of the Orient countries are entirely unaccustomed to use artificial methods for creating a regulated temperature in houses or manufactories.

7597. The ventilation and cleanliness of the nursery or feeding apartments, and the preservation of a regular heat within them, are highly important to the health of the worm. These points are much neglected on the Continent, where the nurseries are usually situated in the midst of the mulberry plantations, exposed to the external air, and seldom cleaned. It was satisfactorily ascertained by M. Guyton de Morveau a few years ago, that a rainswept and unexposed station, which, after being covered with water and dried, was exposed to strong ventilation and illumination, and which has always been protected from a sufficiently large scale in Devonshire, that less mortality prevails among the worms in England than either in France or Italy.

7598. In about six weeks the worm reaches its full size, previously casting its skin four times, and abstaining from food for some time before each change; at these periods the worms are very sickly, and a great mortality generally takes place. When full grown and about to spin, they exhibit symptoms of restlessness and uneasiness; small twigs of birch, or of other slender trees, are set up in the boxes or shelves; upon these the worms climb, each fixing upon its own birch. As it sometimes happens that two worms spin together, forming what is called a double cocoon, this must be carefully prevented by separating them; such a cocoon not only being difficult to roll up when reeled, but two fibres are produced injurious to the size of the thread: the double cocoons are therefore always wound off by themselves. In preparing its case or cocoon, the worm first forms a loose envelopment of silken fibres, and then proceeds to envelop itself in a ball or case of an oval form, and finally changes into the pupa or chrysalis; and after being thus enclosed for about fifteen days, becomes a moth. This, however, is always prevented when the animal is not kept for breeding, otherwise the hole formed by the moth in effecting its escape would destroy the continuity of the silk, and prevent its reeling. The chrysalis are killed by two processes, by baking in an oven, or by letting steam into a tight chest enclosing the cocoons. The latter method is preferable, as the heat can be better regulated.

7599. The cocoon, after the chrysalis is killed, is either reeled off at once, or sold to others who make this a distinct trade. The silk, as formed by the animal, is so very fine, that if each cocoon was reeled separately it would be totally unfit for use; the ends of four are therefore joined and reeled together out of warm water, which softening their natural gum, makes them stick together so as to form one strong smooth thread. When the filament of any single cocoon breaks, or is exhausted, its place is supplied by a new one, so that the united thread may be wound to any length; the single filaments of the new and old cocoons are simply joined by being laid on the thread, to which they adhere by their gum. The old apparatus for reeling merely consists of a large metal basin of water, under which is a fire to keep it hot, and a reel of a poor and even rude construction: some important improvements, however, have been recently made in this machine. In reeling it is desirable that a round thread of equal thickness and smoothness should be produced, having the filaments of which it is composed as equal and as firmly united as possible. When the skein is quite dry, it is taken off the reel, and a tie is made with refuse silk at its two ends; it is then doubled into a hank, and is ready for sale. In this state it arrives in England, and is called raw
Culture of the silkworm in England. It is well known to those who have considered the subject, that the silkworm will breed and thrive very well in England, where the range and extremes of temperature are within narrower limits than in France or Italy. The white mulberry flourishes equally well with us as in those countries. It remains, however, to be proved whether the weight of leaves produced on a given space of ground is equal to the average crop in warmer climates. This is evidently an important consideration, for whether England can compete with foreign countries in the production of raw silk. The high value of land in a country so densely peopled as England, and the fact that the mulberry does not require great extent of ground, but also a clear ground beneath, renders the silkworm a most promising industry, with the prospect of profit from this branch of agriculture very questionable. A joint stock company, in the management of which all the cabinet ministers were more or less concerned, was established in 1769, in the name of "The British, Irish, and Colonial Silk Company." They possessed a very large capital, and had extensive plantations of trees in several parts of England and Ireland, particularly near Windsor and Cork. Mr. John Heathcoat of Tiverton, in Devonshire, has also applied himself to the investigation of this subject. Of the importance of this subject, he said, "The potentiality of this tree was truly liberty of a man, science, he presented to the company several thousand Italian plants destined for his own garden, that he might commence their establishments without delay. If he had been generally known, that the gentleman we are indebted for the discovery of that beautiful art is Mr. John Heathcoat, to whose industry and perseverance the man of culture in England. It was in the attempt to render silk sufficiently even for his use in lace, that he made the discovery in reeling which we have before mentioned; and it is from the result of his investigations that the art of bleaching and mercerising has been perfected. Admitting, as we have done, that no natural impediments exist against the successful culture of silk in England, it will naturally be asked why all attempts hitherto made have been unsuccessful? This question embraces a variety of considerations, which will show that many of the objects we have been endeavoring to attain are unattainable. A number of plantations, to which we have before referred, have been unsuccessful. The unsuccessful attempt of James J. to establish it in England is not accounted for; but the times which succeeded were unfavourable to the introduction of new arts and inventions. The manufacturing of silk goods was introduced into this country in the fifteenth century, and received a great stimulus by the re- vocation of the edict of Nantes in 1685. By this intolerant and disgraceful measure Lewis XIV. drove thousands of his most industrious subjects to seek an asylum in foreign countries; of whom it is supposed not less than 50,000 emigrated to England. From this period the manufacture of silk goods and silk goods, which were hitherto unknown in this kingdom, were established. The mulberry was imported, and even existing plantations, that our climate is not unfitted for the growth of the tree, and the production of the worm, would probably be still more increase in former times. The acknowledged fact that England is much colder than the south of France, or Italy, would naturally indicate, that the mulberry is unsuitable both to the climate and the soil. Individuals who have cultivated the tree have, however, constantly asserted the contrary, and numerous insulated experiments have been brought forward in support of their opinion. Miss Crott of York, in 1790, sent to the Society of Arts a specimen of silk produced by worms fed entirely with an English mulberry. We have before referred to the foreign experiments to prove its quality; and we have already observed that such silk, for purposes of manufacture, is perfectly useless, even in Italy. Yet we know it to be the opinion of men now perfectly conversant with the subject, that the various experiments and trials that have been hitherto made would long ago have succeeded, had we been fully informed on all the requisite points connected with the management of the tree, the worm, and its produce the cocoon.

Our experimentalists have all laboured under one difficulty,—they were ignorant of the reeling process; and this probably arose from their experiments having been conducted on too small a scale to render it profitable. This has been overcame by the exertions of Mr. Heathcoat, at whose establishment in Devonshire the improved method of reeling is now carried on with complete success.

The principal cause of unsuccessful attempts to establish the silkworm industry in Great Britain appears to have been the efforts of the naturalists, who were always exerting themselves to prevent the spread of this destructive insect, and who were continually guiding their efforts to the destruction of the cocoon. After collecting a great quantity of mulberry trees, and establishing considerable plantations in Devonshire and near Windsor in England, and in the vicinity of Cork in Ireland, the company in 1828 gave up the whole, without, in our opinion, having been able to prove, that the worms would produce a silk equal to that of the finest silk, and that the cocoons had been hatched and brought forth in artificial heat even in France, there cannot be a doubt as to the success of this branch of culture in any part of the British islands. Whether it would pay a different thing; but we by no means think it would, even in Ireland.

This common honey bee (Apis mellifica L.) inhabits Europe in hollow trees, but is chiefly kept in hives, being domesticated everywhere. Mr. Heathcoat has been written on the economy of this insect than on any other animal employed in agriculture, and certainly to very little purpose. After all that has been done in England, France, and Italy, the bee is still more successfully cultivated, and finer honey produced, in Poland, by persons who never saw a book on the subject, or heard of the mode of depriving bee or the honey without taking their lives. Much as has been written to destroy the hive in taking the honey. Unanswerable reasons for this practice are given by La Grenou, a French apianist, which are elsewhere quoted by us at length (Emerg. of Gard. art. Bees).
to be conclusive as to profit even by Huish. The honey produced by any hive or apiary depends much more on the season, and the quantity and kind of flowers with which the neighbourhood abounds, than on the form of the hive or artificial management. Viewing the subject in this light, we shall avoid noticing the mode of operating with glass, storing, cellular, or other curious hives of recent invention, and treat only of the simplest methods. The author we shall follow is Huish.

703. The apiary, or place where the bee-hives are placed, should in very warm situations be made to face the east, and in colder districts the south-east. It should be well protected from high winds, which not only prevent the bees from leaving the hive in quest of honey, but they also surprise them in the fields, and often kill them by the falling trees and other causes against the wind. The hives should always be placed in a right line; but should the number of the hives be great, and the situation not capacious enough to admit of their being placed longitudinally, it is more advisable to place them over one another on shelves (fig. 417) than in double rows on the ground. A bee, on leaving the hive, generally comes down from the horizontal plane, to a bee-board, which is usually two feet from the ground, in order to protect it from humidity. The greater the elevation of the hive, the longer is the flight of the swarm; and when they are at a certain point of elevation, the swarms are lost for ever. If the hives are to be placed in a double row, the hinder ones should alternate with, and be placed at such a distance from the front ones, that when the bees take their flight no obstruction is offered to their ascent. Huish recommends placing every hive upon a single pedestal, or two or three feet distance from each other. By this means, when any thing happens to one hive, the others are less likely to be disturbed than when placed on a shelf in a bee-house; and the hive may be chained down and locked (fig. 401). It is usual to put supports to the bee-boards; but those who have tried one will never resort to more, as one is a much better protection from venom and insects. The space in front of the apiary should be kept clear of high plants for two or three yards.

704. The variety of bees employed is a matter of importance. To every species there is a hive suitable. To the common observer all working bees, as to external appearance, are nearly the same; but to those who examine them with attention, the difference in size is very discernible; and they are, as a rule, more active, gentle, and industrious natures, essentially different. Of the stock which Huish had in 1810, it required 890 to weigh an ounce; but they were so vicious and lazy that he changed it for a smaller variety, which possesses much better dispositions, and of which it requires 295, on an average, to weigh an ounce. Whether size and disposition are invariably connected, he has not yet had sufficient experience to determine.

705. The best material and form for hives is a straw thimble or flower-pot placed in an inverted position. Hives made of straw, as they are in use, have a great advantage over those made of other materials, from the effective defence they afford against the extremes of heat in summer and cold in winter.

706. The size of hives should correspond as nearly as possible with that of the swarms. This has not had that attention paid to it which the subject demands. A swarm in the management of the bees depends on that of the hive. From blind instinct the bees endeavour to fill with wax the hives in which they are put into, before they begin to gather honey. Owing to the hive is too large for its inhabitants, the time for collecting their winter store is spent in unprofitable labour; and starvation is the consequence. This evil also extends itself when occasioning the hive being long before the hive becomes so filled with young bees as to produce a necessity for emigration, from which cause the season is too far advanced for the young colonies to procure a winter stock. A full-sized straw hive will hold three bees; a small hive from one and a half to two percent.

707. The Polish hive (Pacieka Pol., fig. 961) appears to us to be the second in merit to that described, and perhaps it may deserve the preference, if the mode of using it were generally known. It is simply a trunk of a tree, of a foot or fourteen inches in diameter, hollowed about nine feet long, and 8 inches below (or would be better) for about six feet from one end, so as to form a hollow cylinder of that length, and of six or eight inches diameter within. Part of the circumference of this cylinder cut off during the greater part of its length, about six inches above and below, and a slip of wood is made to fit the opening. Of this, or of this slip or segment (a) notches are made every two or three inches, of sufficient size to allow a single bee to pass. This slip may be furnished with hinges, and with a lock and key; but procedure is simpler. All that is wanting to complete the hive is a cover at top to throw off the rain; and then it requires only to be placed upright like a strong post in the garden, so as the bottom of the hollow cylinder may be not nearer the ground than two feet, and the opening look to the south. When a swarm is to be put in, the tree, with the door or split opened, is placed obliquely over it; when the bees enter the door is closed, and the holes stopped with clay till the hive is planted or placed upright. When honey is wanted, the door is opened during the finest part of a warm day, when most of the bees are out; its entire state is seen from top to bottom, and the operator, with a segar in his mouth, or with a lighted rag, to lead back of the bees from his hands, cuts out their comb as he thinks fit. In this way fresh honey is obtained during the summer, the bees are never cramped for room, nor does it become necessary to kill them. The old comb, however, is annually cut out, to prevent or less the tendency to swarming, which, notwithstanding this and the size of their dwelling, they generally do once a year; for the laws of nature are not to be changed. Though it be a fact that a small swarm of bees will not do well in a large hive; yet, if the hive is kept in length and not in breadth, it is agreeable to the opinion of Huish that they will thrive in it. "If too great a diameter," says Huber, "be not given to the abode of the bee, it may without danger be increased in the elevation; their success in the hollow trees, their natural domicile, incontestably proves the truth of this assertion."

The honey produced in a head wind will wither the bees, and defer their returns to the bee-board. Hives should be examined in the course of the month of September, or about the time of killing the drones; and if a large hive does not weigh thirty pounds, it will be necessary to allow it half a pound of honey, or the same quantity of sugar, at least, into a bushel of the dry board, as the healthy weight; and in like proportion to smaller hives. This work must not be delayed, that time may be given for the bees to make the deposit in their empty cells before they are rendered torpid by the cold. Sugar simply dissolved in water is the common practice. It is common practice to mix water into a syrup, turn and compound very differently suited for the winter store of bees. When the former is wanted for their immediate nourishment, as in spring, it will answer equally as a syrup; but if to be laid up as store, the heat of the hive quickly evaporating the water, leaves the sugar in dry crystals, not to be acted upon by the trunks.
of the bees. Hives may be killed with hunger while some pounds' weight of sugar remain in this state in their cells. The boiling of sugar into syrup forms a closer combination with the water, by which it is prevented from flying off, and a consistence resembling that of honey is obtained. Howison has lamented the want of a proper experience of bees, not containing the slightest trace of honey, preserved in perfect health through the winter with sugar as prepared, when given in proper time and in sufficient quantity. Sugar so prepared, when given in proper time and in sufficient quantity, 7608. To protect hives from the cold, they are covered with straw, or provided with fur, but, however, at times to remove, by a crooked wire, or similar instrument, a covering which has been lost, or which is not required to shelter the dead bees and other filth, which the living at this season of the year do not continue to maintain, or to those to which a proper quantity of sugar has been applied for that purpose, no further attention will be necessary until the breeding season of the following year arrives. In warm situations, generally takes place about the beginning of May, and should the weather be favorable, require being fed with the same regularity as hives are by their owners; and if the store in the hive be exhausted, and the weather such as not to admit of the working bees going abroad to collect food in sufficient quantity for themselves and their brood, the powerful principle of the main support, at the expense of their own lives. To prevent them to part with what is as to honey and wax, and no great demand for swarms. Bees, however, are but a very small portion of the matter; the others being of no consequence.

The swarming of bees generally commences in June, in some seasons earlier, and in cold climates or seasons later. The first swarming is so long preceded by the appearance of drones, and hanging out of the beehives, that if the time of their leaving the hive is not observed, it must be owing to want of care. The signs of the second are, however, more equivocal, the most certain being that of the queen, and her return, giving out a sound a good deal resembling that of two before swarming, at intervals of about six weeks, at the time when the young ones will have, however, at times to remove, by a crooked wire, or similar instrument, a covering which has been lost, or which is not required to shelter the dead bees and other filth, which the living at this season of the year do not continue to maintain, or to those to which a proper quantity of sugar has been applied for that purpose, no further attention will be necessary until the breeding season of the following year arrives. 7616. The cave or cray fish (Cancer L., fig. 962), called sometimes the fresh water lobster, inhabits still rivers, and forms holes in the banks.

7617. They are said to be nutritious and of an excellent flavour, and are prepared in cooking like lobster or shrimp. In former times they were celebrated for sundry medicinal virtues, but these seem to be now forgotten. The flavour of these animals, nevertheless, depends entirely on the nature of their food. Like all others of their tribe, they feed principally upon flesh. They might be advantageously cultivated in ponds and marshes, but should not be put into fish ponds, as they are detrimental to the fry. A breeding stock may frequently be purchased in Covent Garden market, or procured from any of the small rivers near London; they are also said to be plentiful near Alnwick in Northumberland.

7618. The edible snail (Helix pomatia L., fig. 71. a), although a native of the Continent, has been long naturalised in some parts of England.

7619. It is the largest species found in Europe. The animal being fleshy, and not of an unpleasant flavour, has been used as food from early times. It owes its introduction into England to certain medicinal virtues, no less than to its repute on the Continent as an article of food; but the first of these properties has long since been forgotten, and no progress has yet been made in introducing it on our tables. It is not so abundant in Italy as the common garden snail (Helix aspersa L.), which may be seen, exposed in cages, in the markets of Genoa and other cities. We have no certain information which of these species was held in repute among the Romans, who had their cochlearia or stews, where snails were bred, and fattened upon bran and sodden legs of veal. The H. pomatia is preserved near Vienna in large pits, covered with boards, and fed with cabbage leaves and other vegetables.

620. The medicinal leech (Hirundo medicinalis L.) grows to the length of two or three inches. The body is of a blackish-brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and the lines grow faint, and almost disappear at some seasons. The head is smaller than the tail, which fixes itself very firmly on any thing the creature pleases. It is viviparous, and produces but one young at a time, which is in the month of July. It is an inhabitant of clear running water; but in winter the leech resorts to deep water, and in severe weather retires to a great depth in the ground, leaving a small aperture to its subterranean habitation. It begins to make its appearance in March or April. Water alone is not the natural element of leeches, as it is supposed, but conjointly with ground or mud.

7621. The usual food of the medicinal and trout leech is derived from the suction of the spawn of fish; and leeches will not unfrequently be found adhering to the fish themselves; but frogs form the most considerable portion of their food; hence, the best leeches are found in waters much inhabited by these animals. The medicinal and trout leech do not, like the horse leech, take any solid food; nor have they the like propensity to destroy their own or any other species of the genus; but these the horse-leech will not hesitate to devour. (Natural Journal, vol. iv. p. 361.) If put into shallow clear ponds it will breed freely, and this is practised by some herbalists and apothecaries in the neighbourhood of London.

7622. The use of leeches for the purpose of local bleeding is very considerable. There are four principal importers of leeches in London alone, whose average imports are said to be 150,000 per month each; making a total of 600,000, or seven millions two hundred thousand in one year. On the Continent, where they are obtained at a much cheaper rate, the numbers are very enormous. (Ibid.) The London market is partly supplied from the lakes of Cumberland, where the leeches are caught by women, who go into the water bare-legged, and after a few have fastened, they walk out and pick them off. A good many are also brought from Holland.

Chap. XII.

Animals noxious to Agriculture.

7623. Almost every animal may be injurious to the agriculturist in some way or other. All the cultivated live stock will, if not excluded by fences, or prevented by herding, cat or tread down corn crops or other plants in culture. Those animals, as the dog and ferret, which assist him in deterring or in catching noxious animals which would prey on others, will themselves become depredators if not attended to; and even man, the only rational, and therefore the most valuable of agricultural servants, will prove, under certain circumstances, the greatest of all enemies to the agriculturist. We shall glance at the different animals more especially noxious in the order of their usual classification.

Sect. I. Noxious Mammalia.

7624. Of noxious Mammalia man, in a demoralised state, is the most injurious. The remedy is furnished by the law;—the preventive is good education, and civil and kind treatment by the master.

7625. The fox (Canis Lupes) commits great ravages among lambs, poultry, geese, &c. To destroy it, the farmer must take a sheep's paunch and fasten it to a long stick; then rub his shoes well upon the paunch, that the fox may not scent his feet. He should then draw his paunch after him as a trail, a mile
or upwards, till he gets near some large tree; then leave the poach and ascend into the tree with a gun; and as the night comes on, he may see the fox come after the scent of the trail, when he may shoot him. The trail should be drawn to the tree, if he can space it as fine as possible. Or, set a steel-trap in the plain part of a large field, distant from paths and hedges; then open the pole and fix it to the ground, cut out the exact shape thereof in a turf, and take out just so much earth to make room for it to stand, and then cover it over very neatly with the turf you cut out. As the joint of the turf will not close, put on a mole-hill newly made in some inches square, and stick the trap as it is set, or as it grew there. Scatter some mould of the mole-hill very thin three different ways, at the distance of ten or twelve yards from the trap; let this be thrown on spots fifteen or sixteen inches square; and where the trap is placed, put a very good piece of cheese, or a piece of bread, or a drop or two of oil, and then draw a trail a mile or two long to each of these three places, and from thence to the trap, that the fox may approach one of the places first; then he will advance to the trap more boldly; and you will thus be perfectly sure of catching him. You must take care that your trap be let loose, that he may draw it, or cut it open, and fix it over his off his leg, and then make his escape. The butchery is generally where the fox uses much to resort, fix a stick or pole, much in the same manner as for a woodcock.

To explain these more exactly: tie a string to some pole set fast in the ground, and to this string fasten a small stick, or a stone at each of the lower ends. Next, get a stick or two, or a stone, and set them against the ground, with a nick under it; bend down the pole, and let the sticks or notches join in the slightest degree; then open the nose or string, and place it in the path or walk of the fox. By strewing flesh-meal, pieces of cheese, &c., as you pass along, you may entice the fox to take the same road. 

To shoot a fox, among the sides of the shoes with swine's fat, a little browsed; then go towards the wood, and, in returning, drop here and there a bit of swine's liver, roasted and slipped in honey, drawing after you a dead cat; and by these means he will be allured to follow you. 

The doe is sometimes taken with a box, made of large wire, and turning on a swivel like the collar of a greyhound; it is usually hung so high from the ground, that he is compelled to leap to catch at it; and baited with fresh liver, cheese, &c., and if a trap be run with a sheep's paunch, as before directed, he will be drawn to the bait with the same success. 7628. The pole-cat (Felis Putorius L.) may be caught and destroyed by a dead-fall, constructed in the following manner: Take a square piece of wood, weighing forty or fifty pounds: bore a hole in the middle of the upper side, and set a crooked hook fast to it; then set four forked stakes fast in the ground, and lay two sticks across, on which to put the dead-fall, to hold the crook of the hook. Place the dead-fall up to this crook put a short stick, and fasten a line to it: this line must run down to the bridge below; and this bridge you must make about five or six inches broad. On both sides of this dead-fall place boards or pallets, or put some sweet-smelling earth on them, or any other artifice to keep the fox from passing over it. Fix a stick or pole, as before, at right angles to the breadth of the dead-fall. A pigeon house, surrounded with a wet ditch, will tend to preserve the pigeons; for beasts of prey naturally avoid water.

7629. The weasel, or Euraert (Felis vulgaris L.), though in some respects beneficial, in as much as when destroying mice, and other noxious vermin, is nevertheless, in a wild state, a formidable foe to poultry and rabbits. Weasels may be destroyed by putting in their haunts small pieces of paste, consisting of pulverised sal ammoniac, mixed up with the white of an egg, wheaten flour, and honey, which being put in round by the weasel nestle, it is said to drive away these our visiters; as also will the smell of a burnt cat; as all animals are terriified at the burning of one of their or of a similar species.

7630. The badger (Ursus Miles L.) destroys great numbers of young pigs, lambs, and poultry, every year. Fix a dead-trap, or a steel-trap, such as foxes are taken in, to catch them. Others sink a pole, five feet in depth and four in length, forming it narrow at top and bottom, and wider in the middle; then cover it with small sticks and leaves, so that the badger may fall when he comes on it. Foxes are sometimes taken in this manner. Others, again, pursue a badger to his hole, and dig him out: this is done by moonlight.

7631. The mole (Tupa europea) is injurious by the subterraneous roads and hills of earth which it forms in grass lands. With regard to the removal of holes various practices are in use; but the most effectual is that derived from the experience of a successful mole-catcher, and communicated to the public by Dr. Darwin, in his Phylologis. This man commenced his operations before sun-rising, when he carefully watched their situation; and frequently observing the motion of the earth above their walls, he stuck a stick in the ground at right angles to their retreats; but he then dug the ground near their holes, usually place their nests at a greater depth in the ground than their common habitations, and thus form an elevation or mole-hill, the next step is to destroy these nests by the space; after which the frequented paths are to be distinguished from the bye-roads, for the purpose of setting subterraneous traps. This object may be effected by a mole-hill with two or three holes made in the middle of the mole-hill with quite long pole-tracts, one over the other, and observing the next day whether a mole has passed over it, and destroyed such mark; and this operation should be repeated two or three mornings successively, but without making the pressure so deep as to alarm the mole unless four of our complete and be opened. Now, the trap are to be set in frequented paths, and should be made of a hollow wooden semi-cylinder (fig. 9)2), each end of which should be tur- nished with groved rings, containing two nooses of horse-hair, that are loosely fastened in the centre by means of a peg, and are stretched above the surface of the ground by a buttc stick or strong hoop. As soon as the mole passes half way through one of these nooses, and removes the central peg in its course, the hoop, or bent stick, rises in consequence of its elasticity, and of course strangles the mole. The simplicity of this mode of destroying mole-hills and moles recommends itself to general adoption, as those whose grounds are thus infested may easily estimate them, by teaching this practice to their labourers.

7632. The domestic or Norway rat (Mus Rattus L., fig. 905.) is now generally diffused throughout this country, where it has almost extinguished the indigenous wild rat. It is extremely noxious quadruped, as it devours the live and dead stock of the farmer. The following methods for destroying it are preferable to all others, and are given in Wellers's Domestic Economy, vol. iii. — Fry a piece of sponge with salt butter in a little pan. This sauce compasses it between two plates and plates, and scatter them about the holes frequented by rats and mice. This preparation is devoured with avidity; it excites thirst in the stomach which should be grained with a little black licorice or drying water. On drinking this fluid, after having swallowed the burnt sponge, it deters their stomach, and provokes a fatal re- part. — Or, a capacious cask of moderate height must be procured, and put into the same position. During the first week the process is one of ensnaring the rats to visit the solid top of the cask, by means of boards or planks arranged in a sloping direction to the floor, which are every day strewn with oatmeal, or any other food equally grateful to their palate; and the fluid is freely poured over the surface. After having been accustomed to find a regular supply for their meals, a skin of parchement is substituted for the wooden top of the cask, and the former is cut for several inches, with transverse incisions through the cask, so as to yield on the smallest pressure. At the same time, a few gallons of water, to the depth of one or two inches, is poured into the empty cask, so as to project, one or two inches above the fluid; and that one rat may find on the former a place of refuge. These preparatory measures being taken, the boards as well as the top of the cask should now be furnished with proper bait, in order to induce them to repeat their visits. No sooner does one of these marauders plunge

B 3
through the section of the parchment into the vessel, than it retreats to the brick or stone, and commences its lamentations for relief. Nor are its whimpering notes uttered in vain; others soon follow, and share the same fate; when a dreadful conflict begins among them, to decide the possession of the dry asylum. Battles follow in rapid succession, attended with such loud and noisy shrieks, that all the rats in the neighbourhood hasten to the fatal spot, where they experience similar disasters. Thus hundreds may be caught by a stratagem, which might be greatly facilitated by exposing a living rat taken in a trap, or purchased from a professional rat-catcher.

7655. A successful mode of enticing rats has been lately practised by Broad, a farmer at Thruston in Herefordshire. He uses a bare trap, two feet long, eight inches wide, and nine inches deep, and little different in construction from the common one. His secret consists in scenting light-coloured malt, and also some wheat straws, with oil of caraways, and not setting the traps for a day or two till the rats have been accustomed to eat the malt without fear. (F. Mag. xiv. p. 43.)

7654. Paul of Starston's rattery was thus described by S. Taylor, Esq. in the Gardener's Magazine:

''This rattery was invented by Mr. R. Paul of Starston, in Norfolk. He bestowed much labour and time to bring it to perfection; and, though living in a situation particularly favourable for encouraging the breed of rats, used to boast that he had completely subdued them. In fact, I have heard him say that he offered a reward to any one who would bring rats on his premises; and that having marked and turned off one particular pair, he betted a wager that he should soon catch them both; which, in the course of a very few days, he did. He selected, as the site of his rattery, some outhouse where rats were known to frequent, and which he could lock up, and keep sacred to his own devices and operations. Here he fixed his trap, the construction of which will be best understood by referring to the accompanying sketches (figs. 961, 962). This

The same letters refer to each of the figures.

spot he endeavoured to make as inviting and comfortable to the rodent as possible; for which purpose the flagged pepper, loose wood, and even straw, with an occasional wheat sheaf, and a little bait thrown at the roots of the trees, would form a complete thoroughfare; for which purpose the trap or falling bottom (a) was, for several days, secured by a pin, and the end

967

7656. The beauty of Paul of Sturton's trap is, that, when once set, and the catch (r) regulated to its proper pitch, it requires no further trouble. One is sufficient for the whole premises. The great object is, to give them time enough to get acquainted with it, for which purpose every thing should be done to induce them to the spot, and to make them feel themselves at home. A little pale malt, slightly finetured with water, put in places the most inviting dish is commonly given to them before; and it will be well to bear in mind, that no part of the trap, not even the straw or the wood by which it is surrounded, ought to be touched by the naked hand without first rubbing the skin with a portion of the sand of the country. Do not scatter the malt sparingly under the bridge (g), but spread carelessly, as it were, about the feeling end of the trough (m). It will thus be in sight from the other end (a); and, to get it, the rats must pass the bridge (g); for it will be seen at fig. 964. B. If, that the entrance to the trap is now (by means of the wood placed at the end of the trough (a), although at first it had an entrance at each end, and, as I have stated, a complete thoroughfare. Inad it, some have them on this plan still; having no particular feelling hand. Trusting entirely to time and chance for what they may catch; having first taken pains to make the trap an a, and the place itself a harbour for rats. I do not know that it is requisite for me to add more words. The drawings sufficiently explain the principle; and as to dimensions, these can be determined by the projector, and rat, in some degree, depend on the size and conveniences of the building to which the ratter is attached. The trap itself should not be above three or four inches wide, and twelve or fifteen inches long; in order to allow plenty of room for the fall of a large rat. "The forlorn hope" into which he dropped from

968

7677. The long-tailed field mouse (Mus sylvaticus L. fig. 969, a), and the short-tailed field mouse (b), are both rather larger than the common mouse. Of late years they have appeared in vast numbers in some parts of England, and caused considerable damage to the agricultural produce. In 1814, and the following year, the extensive plantations in Dean and New forests were nearly destroyed, over an extent of five hundred acres; the devastation was caused by these termite attacking the five-year-old oak and chestnut trees; and

969

we shall describe. The pits were made from eighteen to twenty, the holes deep at the bottom, feet in length, and one foot in width; and, at the top, only eighteen inches long and nine wide, or, indeed, as small as the earth could be got out of a hole of that depth; for the wider they are below, and the narrower above, the better they answer their purpose. They were made twenty yards apart from each other, and the less numerous the better. By this method thirty thousand mice were caught in a short time, but a far greater number had been taken out of the holes, either alive or dead, by stoats, weasels, cats, and, especially hawks. It was for a long time supposed that this damage had been done by mice and rats; and it is now generally admitted, that the similar injuries are frequently attributed erroneously to these animals. Some years ago an extraordinary quantity of mice created similar devastation in Lord Began's extensive woods in Staffordshire, and in those of Lord Downes in Yorkshire (Zoologist, No. 4. p. 42). Of the Dean, had become so destructive in 1813, that after trying traps, baits with poison, dogs, cats, &c. with little success, at last the plan of catching them by holes was hit upon. These holes were made from eighteen inches to two feet long, sixteen or eighteen inches deep, about twenty yards apart from each other, and the bottom only six inches longer at the bottom than at the top. The object was to get the bottom of the hole three or four inches wider every way than the top, and the sides firm; otherwise the mice would run up the sides and get out again. The holes were made at twenty yards apart each way, and each side of a surface of all the trees, and were freed from them for two or three years. As many as fifteen have been found in a hole in one night; when not taken out soon, they fell on and ate each other. These mice, we are informed, used not only to eat the acorns as they newly shunted, but to travel through the stems of trees seven and eight feet high, and one inch and a half in diameter; the past catch being in the time, or seat of live. (Ballington's Facts on Oaks and Trees, 2d. p. 43.)
Sect. II. Birds injurious to Agriculture.

7639. Of birds, the most decidedly injurious to man are the different hawks and kites, as well as the species attack and devour young poultry.

7640. Various methods have been proposed for remedying this evil, but they evince little acquaintance with the habits of these birds. Mr. Swainson recommends that the prevalent custom, of nailing such as have been killed against barn-doors or outhouses, he exchanged for the following:—In such parts of the country as are frequented by these birds, let two or three poles, ten or twelve feet high, be placed in the farmer's poultry yard, each pole being furnished with an iron spike six or eight inches long; pass this spike through the body of a dead hawk in the direction of the back-bone: it will thus be firmly secured, and give the bird an erect position; the wings being free will be moved by every breeze, and their unnatural position will prove the best scarecrow either for ravens or granivorous birds, more particularly the latter. Destruction by the gun is of course the most effectual.

7641. Whether granivorous birds are more injurious than beneficial to the farmer, is very questionable.

7642. The crow, rook, raven, sparrow, magpie, and starling are commonly called granivorous; yet this is an error, for these birds feed but little upon animal and vegetable substances, and more particularly upon insects. We are annually told of large crops being either wholly or partially destroyed by insects of some sort or other; but we never hear that these injuries have been occasioned by birds. These complaints have certainly been more numerous of late years than formerly, and this is attributed by Mr. Swainson to the destruction of small birds (as waste lands are brought into cultivation); to the great diminution of rookeries; and to the foolish prejudice which the generality of farmers have taken up against these latter birds, which they destroy without mercy. In this instance we have been less wise than our ancestors, who protected and cultivated them, and by whom they were justly considered of the greatest benefit to mankind. Nature seems, indeed, to have pointed this out to us, for she has distributed the crow in all parts of the habitable world. Yet the farmer will enquire, "What good can these birds do me, when they come upon my newly sown land, and root up the seed?" The answer is very short. The only crops which do not come for the express purpose of eating or destroying the seed, but for devouring the insects, snails, and grubs turned up by the plough or harrow; these are their favourite food, and while so occupied, the small quantity of seed they may eat or displace is returned to the farmer tenfold by that saved from the insects. Mr. Wallis, in speaking of the destruction caused by the hedgehog or cockchafer, says, that "whole meadows and corn-fields were destroyed by them;" and judiciously concludes by observing, "that the many rookeries with us is the reason why we have so few of these destructive insects." (Hist. of Northumberland.)

Sect. III. Insects injurious to Agriculture.

7643. Insects, above all other animals, are by far the most injurious to the agriculturist; not only from their numbers, but from their attacking the produce of the earth in all its stages of growth and maturity. We have already pointed out the advantage, not to say the necessity, of a certain knowledge being acquired respecting insects, by all persons engaged in agricultural pursuits. We shall now explain, in popular language, the different tribes and orders into which they are divided; the changes they undergo; and the injuries they produce to man, and the animals and vegetables which he cultivates.

Numerous insects, much more destructive than those we shall enumerate, are found in other climates, but from which the British agriculturist has, happily, nothing to fear, and therefore need not be acquainted with. The reader will, however, find much valuable information respecting them concentrated in Kirby and Spence's Introduction to Entomology, vol. i.

Subsect. 1. Physiology of Insects.

7644. Insects are distinguished from worms (Termes L.) by always having feet in their perfect state, as the beetle, butterfly, &c. Worms crawl upon their bellies and have no feet, as the earthworm, slug, snail, &c. The generality of insects have only six feet; but some few, generally called by this name, have a great many, as the woodlouse, isopede, &c.

7645. Nearly all insects are oviparous; that is, produced from an egg. These eggs are seldom found singly; they are small in size, and do not grow. The eggs of some species are hatched in a few days, while those of others remain during the winter, and the young do not come forth until the season at which the leaves of the plants upon which they feed begin to expand.

7646. The second state of the insect is called the crèpe, or larva in systematic language, and is known to the vulgar as the caterpillar. This name, Caterpillars are those larvae which are exposed, and feed upon leaves and plants, as the caterpillar of the common butterfly (fig. 971. a). The larvae of beetles usually live in the earth, in the trunks of trees, or in the substance upon which they feed; they are generally of a whitish colour, thick and clumsy in form, and are called grubs. The larva of the common cockchafer (fig. 750. b), and of the nut-beetles (fig. 691. c), are of this description; while the name of maggots is usually given to the larvae of flies, bees, ants, &c., all of which live in the same confined state as the maggots of beetles. It is in this stage of existence that insects are most voracious, and consequently most destructive to plants. In this state, instead of leaving its case of pupal skin, and changing into its full size, it changes into the pupa or chrysalis state. This is done in different situations, according to the tribes to which they belong. The chrysalis of butterflies (fig. 971. b, c) are naked, and are either suspended or attached to trees, branches, walls, &c. Those of moths are either concealed in a case like the cocoon of the silkworm, or the caterpillar undergoes its change in the earth. The period in which insects remain in this state varies according to the species; but in most cases they are inactive and torpid.

7648. The imago, or perfect insect, is produced from the chrysalis, and is the only state in which all its parts and members are fully developed. The appearance and economy of perfect insects, in general, is totally different from those of the larvae and pupa, and it is only in its final stage of existence that the species can be ascertained. With the exception of such insects as form the A pteria of Linnaeus, all others are furnished with wings, either four or two in number. Some few exceptions, however, occur to this rule; the females of the glow worm, and of some few moths are aposematic, while many beetles (although furnished with hard winged cases) are destitute of real wings.
7649. The duration of insects is extremely variable; the greatest proportion appear to be annuals emerging from the egg and passing through the three stages of their existence within the space of a year. But there are a great number of species, particularly among the beetles, which pass three, and even four, years in the caterpillar state; and instances are on record of beetles remaining in timber from ten to fifteen years. The greatest proportion of moths are biennial, passing the winter in the chrysalis state and closing their existence in the succeeding summer. The transitory life of the Ephemerata is proverbial; the perfect insect indeed exists but for a day, and seems born only to continue its species; yet in the larva state it enjoys a life of one, two, or even three years.

Subsect. 2. Arrangement or Classification of Insects.

7650. All insects, as Macleay observes, may be divided into two groups: 1. Apterous insects, having either no metamorphosis, or only that kind of it the tendency of which is confined to the increase of the number of feet; these, as their name implies, are destitute of wings. 2. True insects, or those whose metamorphosis has a tendency to give wings to the perfect or image state, but never more than six feet.

7651. True insects are again divisible into two primary groups; the first of these are organised for mastication in their perfect state, and the second are organised for suction alone. Each of these divisions, according to the system of Macleay, contains five separate orders, the principal characters of which we shall endeavour, as far as we are able, to make intelligible to our readers.

7652. The Mandibulata, or masticating insects, are furnished with jaws of a horny or membraneous substance, infinitely diversified in their form and structure. They are divided into the following orders: —

1. Trichoptera. The wings are four, soft, and generally transparent; the upper pair slightly hairy, and the lower folded when at rest. The insects of this order are comparatively few. The cadis, or cadis worm, is the larva of the spring fly (Phryganea), and lives in the water, concealed within a tube of its own construction. There are many species in this country, well known, in their perfect state, to all lovers of angling. Three species (fig. 967.) may serve as an example of this order.

2. Hemiptera. The wings are four, clear and transparent. The tergus (or outer division of the foot) is composed of five joints, and the body is armed with a sting. The bee, the ant, and the wasp, are familiar examples.

3. Coleoptera. This well defined and most extensive order comprehends all insects known by the name of beetles. They have two wings, concealed beneath a pair of hard wing-cases, which must close together in a straight line down the back. There are many tribes of these insects, which, both in their larva and perfect state, are extensively injurious to man.

4. Orthoptera. The true wings are but two, very large when expanded, and folded lengthways when at rest. They are covered, either entirely or wholly, by two wing-cases of a thin, tough, and rather opaque substance, somewhat resembling parchment, and reticulated with small nerves. The leading characters of this order are exemplified in the Blatta, or cockroach; the pest of tropical countries, and frequently troublesome in our kitchens and larders.

5. Neuroptera. The wings, with very few exceptions, are four in number, clear, transparent, and reticulated with numerous areolæ, or irregularly square divisions; the tail of the female is not armed with a sting. Few, if any, of these insects may be considered as injurious; some are, indeed, beneficial; as, from their predatory habits, they attack and devour a vast number of smaller insects. This is more particularly the habit of the green dragon-fly (Agyris virgo, fig. 967. a), which every one may see, during summer, hovering over ponds, and flying about like a hawk in search of its prey. The Ephemerata, or damselfly (E. virgata, fig. 967. b), likewise belongs to this order; and, although not so common in this country, is so abundant on the Continent, that they are collected annually in barrels, and afforded to the agriculturist a rich and valuable manure.

7653. The Hymenoptera, or suctorial insects, likewise contain five orders. Although apparently destitute of jaws, there is every reason to believe, from the observations of the celebrated Sayvigny, that the rudiments of the masticating organs exist in these insects, but that they are so slightly developed as to be totally useless, and only discoverable under a very strong magnifier. The suctorial insects in their larva state are mostly furnished with strong and well defined jaws, and feed voraciously upon animal and vegetable bodies; yet, from the perfect insect being supported by suction alone, it is obvious that in this state they can do no injury to the agriculturist. The orders into which they have been divided are these: —

1. Leptoptera. The wings are four, thin, membraneous, and covered with a fine powdery substance, which, by the magnifying glass, is shown to consist of minute scales, lying one upon another, like those on fishes. The butterfly and moth tribes are familiar to every one, as well known examples of these insects, the larva of which are called caterpillars. The Papilio (fig. 967. a), the peacock (fig. 967. b), the rose-bush butterfly (fig. 967. c), the cabbage white (fig. 967. d), all serve as a good example of the egg (e), larva (f), and pupa state (g) of most day-flying lepidopterous insects.

2. Diptera. The wings are two, clear and transparent, like those of the common house-fly. This order is very numerous, and contains many insects which are injurious to vegetable and animal life, and troublesome to man in a winged state; as the horse fly, the stable fly (Tabanus), commonly called Tsetse, &c.

3. Apynta. Entomologists of the last century arranged all insects without wings under this order; but it is now restricted, by Latreille and Macleay, to such only as have a halve articulat ed sheath to their mouth or nostrum, and no wings, as in the case of the common flea.

4. Hymenoptera. These insects of this order are furnished with two, three, or sometimes four pairs of wings, the middle pair being concealed under each other, of a semicircular substance, and which are likewise useful as organs of flight. The tergus are composed of three, two, or sometimes only of one joint, and the body is much flattened. The various insects commonly called bees, wasps, &c. emit a strong and disagreeable smell when handled, are all arranged under this order.

5. Homoptera. These insects have a great resemblance to the last; but the body, instead of being depressed and flat, is

Book VII. INSECTS. 1118
the name of bots. They attain their full size about the latter end of May, and are voided by the anus from that time until the end of June. On dropping to the ground, they find out some convenient retreat, where they change into a chrysalis; and in six or seven weeks the fly appears. The female (b) is distinguished from the male (a) by the lengthened shape of her body. The inside of the knee is chiefly selected for depositing her eggs, which will frequently amount to four or five hundred on one horse. The other species (E. hemorrhoalis L.) is still more troublesome; it deposits its eggs upon the lip, and causes excessive and distressing uneasiness to the animal. Mr. Bracy Clark, who has investigated the history of these insects with great ability, observes that in ordinary cases it is not improbable that they are beneficial to our cattle, by acting as perpetual stimuli or blisters; yet, when they exceed certain limits, they produce disease, and sometimes death. (Clark in "Linna. Trans. vol. II.) The prevention of bots belongs to the farmer, the cure to the veterinary surgeon. The first may be effected by watching the animal at the season when the female deposits her eggs (usually in August and September), and should the horse appear much agitated in its pasture, there will be good reason to suspect it has been attacked by the fly; the eggs may then be removed by the brush and currycomb, or by a pair of scissors. When the disease is certain, one of the best methods to destroy the insect is to fasten a bag net on the horse, for the purpose of catching the excrement, as well as the full-fed larva. By throwing the dung every morning into a deep pit, any grain that may be encased in it will thus be prevented from working its way to the surface. When their last transformation is about to take place, and their death will cut off a numerous progeny. There are other dipterous insects which feed upon the blood both of horses and cattle; the most formidable of these are the horse flies (Tabani, &c.), others, much smaller (Stomoxys eletttrans), assail him in every situation during summer, and dart their long proboscides into his legs and belly. But none are more trying to him than the forest fly (Hippobosca equina L.), which runs sideways or backwards like a crab, and makes itself so firmly in those parts least covered by hair: it may, however, be caught by the hard, when the animal is in his stall; but its substance is so hard, that it can only be destroyed by rolling it between the finger and thumb.

7657. Horned cattle are likewise subject to the attacks of a peculiar species of gad-fly (E. bowis, d, f, g), which causes them great terror and distress. The larva (e) is smooth and cut (d) and the chrysalis (f) opens by a lid m when the insect (d) emerges from it. The herdsman may know when this insect appears among his flocks, by the agitation they exhibit; the whole herd, with their tails erect, or carried in some grotesque attitude, gallop about and utter loud howlings. When oxen are employed in agriculture, the attack of this fly is often attended with danger, as they become quite unmanageable, and, whether in harness or yoked to the plough, will run directly forward. Their harness at this season should therefore be so constructed as to be easily loosened. The eggs are deposited within the skin of the animal, and in a wound made by a tube resembling an auger, with which the female is provided. These flies only attack young and healthy subjects; but, independently of the terror they create, do not appear to occasion any material injury. The cattle of Hungary and the neighbouring countries, as also those of Abyssinia, are subject to more deadly enemies, which fortunately are unknown in England.

7658. Sheep are also infested by another species of gad-fly (E. ovis L., h, k, l, m) which deposits its eggs in the inner margin of their nostrils. The moment the fly touches this part of the sheep, they shake their heads, and strike the ground violently with their fore feet; at the same time, holding their noses close to the earth, they run away looking about them on every side, to see if the fly pursues; they will sometimes crowd together in a rut or dusty road with their noses close to the ground. The larva (h) are white, flat on one side and convex on the other; they inhabit the cavities of the maxillary sinuses, when the animal is dead, into those of the horns and frontal sinuses; when full grown, they

Part II.

22
through the nostrils, and change to the chrysals (h), which produces the fly (g) in about two months. Swine, pigeons, and all kinds of poultry are subject to lice, and live of various kinds, but never to such a degree as to occasion death.

765. Flies, like their fry or fry state, are the food of the larvae of water beetles (Dytiscid). These insects are frequently seen in great numbers in ponds: they may be caught by a hand net (made of very small meshes), inserted beneath the insect, as he reposes (with his head downwards) on the surface, and then suddenly drawn upwards.

SUBSECT. 4. Insects injurious to Vegetables.

7660. The ravages of insects upon plants commence from the time that the seed is committed to the ground, and continue until the produce is gathered into the barn. These various injuries, in one shape or another, are visible to all, beyond all doubt, while those that do not to an alarming extent, if the great body of agriculturists persevere in their mistaken prejudice against cows, rooks, and other useful birds, which Providence has kindly given us, to keep the insect tribes within due limits, it is possible that many of the insects which are injurious to our succulent plants, as wheat, barley, &c. in a general way (Part II. Book VI.) we shall now enumerate those that infect the grains, clover, pastures, cabbages, and plants, and fruit-trees, as well as those universal destroyers of all vegetables, the wire-worm, the plant lice, and the different species of crane-fly.

7661. Wheat, in every state, is subject to many insect depredators. The wire-worm (by some mistake for the wire-worm), which eats into the young plant about an inch below its surface, devours the central part, and thus causes its immediate death. Out of fifty acres sown with wheat in 1810, ten had been destroyed in this way so early as October. At a later period this grain is attacked by a fly nearly related (according to Mr. Kirby) to the Mollusca arcuatus of Latreille. It makes a lodgement in the heart of the principal stem just above the root, which stem it invariably destroys, giving the crop at first a most unpromising appearance; but it proved ultimately that the plant, instead of being injured, derived great benefit from this circumstance. For, the main stem having perished, the root (which was not hurt) threw out fresh shoots on every side, so as to yield a more abundant crop than in other fields where the insect had not been. When first observed in England, this insect caused great alarm among agriculturists, who thought it might prove the Hessian fly. But when the when the destructiveness of the attack on a small orange-coloured grout, which deposits its eggs in the centre of the flower; the larva or grub devours the pollen, and thus prevents the impregnation of the grain. The weevil, a small coleopterous insect (Calandra granaria L.), is extremely destructive to wheat when in the granary, and has been very injurious against the first, second, and third crops of various sorts; as it lives in the grain; but as this is larger than the perfect beetle, the latter may be in a great measure collected by means of a sieve, large enough for the insect (but not the grain) to pass through: it is often found infesting the stored and delayed harvest. The grain is therefore very near it, often infects sea biscuit; and can only be killed by baking or heating the biscuits over again in an oven.

7662. Ryegrass is subject to the attacks of a small fly (Masca panhminis), which introduces its eggs into the heart of the shoots, and occasions a loss of from eight to fourteen plants in a square of two feet. No remedy has yet been proposed for this pest, which, if not extensive, may be checked by plucking the injured ears, and burning them.

7663. Barley, besides other insect foes, has one peculiar to itself, in the shape of a small moth (Tinea hordell K.). This fly deposits from twenty to thirty eggs on a single grain; when hatched, each of the larvae disperses, and selecting a grain for itself, enters from without, and lies totally concealed; should these moths be numerous, the grain may be stopped by carefully removing the grain, leaving a few handfuls exposed; upon these the moths will deposit their eggs, and by roasting or destroying this small quantity, the rest may be saved from infection.

7664. Oats are subject to few diseases; but, like all other grain, the plants are liable to be destroyed by that universal devastator the wire-worm, of which a more particular account will be found in treating of insects universally injurious to vegetables.

7665. The diseases of peas are mildew and blight, but these are only occasional; its insect enemies, however, have been much more frequent. In this last respect, the plant house (Apis hajalis) is in some respects similar to this plant. In the year 1810, the crops of peas throughout the whole kingdom was so much destroyed by it, that the produce was not more than the quantity sown; and many farmers turned their swine into their pea-fields, not thinking them worth gathering. (Kirby and Spencer, i. p. 177.) Beens are extensively attacked by a black fly (Aphis of a black color), which turns the plants black, withers the plant, and multiplies downwards. In both cases the most effectual remedy is to top the plants at an early period of the infection, and burn the parts so gathered; this plan is likewise advantageous, as it improves the bean, and allows the ears or pods to fill; while the beetles, in escaping this pest; or if a small quantity of quick-lime is sprinkled upon them when they are a few inches high, experience has shown that the plants remain uninjured, while the Aphis is totally destroyed.

7666. The diseases of beans are the rust, honey-dew, and mildew. The insects which infest it, and its eradication, have already been noticed. (2563.)

7667. Turnips are subject to several peculiar diseases, and are the food of manynoxious insects. On the first appearance of the cotedil leaves, a whole host of little jumping beetles (Hepica nymmosomor), called by farmers the fly and black-worm, attack and devour them, so that the land is often obliged to be resown. An eminent agriculturist has calculated, that from this cause alone the loss sustained in the turnip crops of Devonshire in 1780 was not less than 10,000l. (Young's Annex, vii. p. 102.) Nearly as numerous is the Mouse-beetle (Curculo contraria Mauhlan), which infests the peas in the same manner, pieces a hole in the cuticle; with watering lime, &c. may serve to check both these evils.

7668. The caterpillar of a saw-fly (Tenthredo La), entirely black, moves about as soon as they have produced three or four rough leaves; these have sometimes occurred at the same time on the same plant; when many thousands of acres were, on this account, plundered. These caterpillars are sought, as a general practice, and the whole crop plundered by the wrens, crows, rooks, and magpies, that those farmers, whose good sense had led them not to destroy, but rather to encourage, the birds which otherwise would have proved no small pest. To destroy it in the most effectual way, watering or splashing the plants, with water, or with a solution of Eau-de-Camt, when the eels have not quite emerged, is the best method of exterminating this insect.

7669. To destroy the caterpillar of the turnip butterfly (Tetuina hypef A.), which is to be met with in the root of the turnip, and destroys its surface, the neck of the grub, which so much resembles the wire-worm, and which, unless before alluded to (765), have been found by the leaves of the turnip in a similar manner, is much more injurious. The turnip is liable to many external and internal diseases: by the first term we must be understood as alluding to injuries caused by insects, while those which belong to the vegetable are certainly internal. When the plants first emerge above the ground, they are infested by the small beetle, vulgarly called the turnip weevil in a more advanced state the tops and branches are devoured by the hop Aphis, known to some by the name of the green fly, while at the same period the roots are subject to the attack of the caterpillar.
of a singular species of moth, named by collectors are
crude, the dew, the mull, the blight, and the
tough mostly when the plant is full grown.

7675. The hop insect, improperly called the hop, has no other residential that it is small, and jumps. It
is, on the contrary, a beetle (Halticus connor), of a species
unknown, and not at all a hop insect. In its per-
fect state it commits great havoc, by eating the tender shoots of
the hop; it has been said, this insect absolute
most in seasons when the nights are cold, and the
days hot and dry. Others assert, that it is most frequent on plants in
greenhouses, and that it has been dined on the same, on which ac-
count it has been recommended, that the mature use for
covering may be either sprinkled on, or pounded as before
mentioned (1915), and applied either over all the land, or only on the
particular species attacked. It is quite apparent it does not appear to
have originated in a due knowledge of the subject. Nothing
as yet appears known regarding the nature or inhibition of this
insect, other than that it will devour the hop stems, and unless it is acce-
tiated to live, during that period, in the aerial plane will
be very destructive. The destructive effects of hop injury
insects, however small, has been extensively proved, and should be
handled with the utmost care, with the view of the value of the crop
will bear the expense of its application. Mr. Samuel Curtis has stated
in the Horticultural Magazine (p. 46, part II. p. 124) the very great advantages it has derived by applying
patronized quicklime to fruit-trees; and there is no doubt that the
same good results would be equally successful, if extended to the
turnip and hop plants, so soon as the young leaves begin to ap-
pear, or the first symptom of their being attacked by this insect.

7675. The hop insect, called by some the green or long-winged, is a species of Alphis peculiar to the plant; it makes its
appearance towards the end of May, and during the two next
months. These insects are rather small, but they have then every advantage of being less
tolerable to the hop parry, and the white purple
clover are often devoured by the same little jumping beetles (Halticus F.) which attack both turnips
and hops.

7675. Clover is very subject to be injured by a very small weevil (A'pion flavifemorium K.), which at
all seasons feeds upon the seed of the purple clover, while another species of the same tribe (A'pines)
devours that of the white or Dutch clover; the injury, unfortunately, cannot be known while the plants are
in the ground, as they have then every advantage of being unseen, and the white purple
clover are often devoured by the same little jumping beetles (Halticus F.) which attack both turnips
and hops.

7675. Pastures in general are destroyed to a very great extent by the larva or grub of the cock.
chafers (50. a), known in different parts of England by the following provincial names:—Brown tree-beetle, blind beetle, Jack horner, Jeffy cock, May bug, brown-clock, dor, and miller.

7675. The ravages of the horse are even
even greater than those of the perfect insect, which
sometimes appears in this country in prodigious
t multitudes, and, like a flight of hawks,
devour every thing on the face of the earth. The eggs of this terrible devastator are white, and are either disposed in the ground, or
they soon change into a soft whiteish grub with a
mouth about an inch and a half long (9). In this state it
continues four years, during which time it commits most destruc-
tive ravages on the roots, not only of grass,
but of all other plants and young trees. Whole
areas of the richest pastures are thus converted into
an unproductive; all verdure is lost, and the
turnip plant is almost wasted with so much energy
if it had been cut with a spade. The whole
of the roots of the pastures being on under ground, admits neither of prevention nor palliative
measures; but the destruction is to be expected from the moment the insect may be prevented.
If the dried and withered turf is now
removed, and the underground part will appear
in a soft mold for about an inch in depth, like
a garden: in this condition it can be grown
and the grubs will be found the grubs, lying on their backs in convulsed position, and the
quantities may be gathered and given to pigs and poultry. It is grown, the larvae in the earth to the
almost incredible depth of five or six feet, spin a smooth case, and meander through the ground;
this in form they remain until the following spring.

7675. The insect infest a place comes from the ground,
and commences an immediate attack upon the leaves of all
numbers are sometimes so immense, that, was it
not following the account fully authenticated, we should
more doubt its correctness. In 1888, the cockchafers appeared upon the
brooms and hedges in the counties of Glosters in thousands, clinging
to each other, and in the manner of bees, they swarmed. During the day
the insect remained quiet, but towards sunset the whole crowd was in
motion, and the numbers of the insects, as to appear to be
increasing. Their numbers
were so prodigious, that for the space three miles sixty
from the air, and the noise they made in devouring the
leaves was heard to have been heard even to the
sawing of timber. In a very short time the leaves of all
the trees were covered with a blanket of leaves in
in the middle of summer, as dried and desiccated as it would have
been cut with a knife. Many of these insects have devoured them in
unnumerable; they waited under the trees for
the crowning
7675. Cabbages and other excellent vegetables are well
known to be greatly injured by the caterpillars of
two different kinds of white butterflies (fig. 157.), one of these (Plieris brassicae, c) is much larger than the other
species which is pale yellow, with black spots (a); when full fed, it shelters itself on walls, pales, or
grazing on round the stems of plants, and on its
trunks of trees, and clambering up to the top, the chrysalis state is in an
the same colour; and the butterfly (f) is produced
from the same chrysalis: the caterpillar (d) has the
other wings, the wing tip being attached to the
was, or are, and in many cases sufficiently ridiculous: handpick the larva, and screening for
the chrysalis, are the only plans we can recommend, either for these or the gooseberry and current
caterpillars.

7675. Fruit trees of all kinds, and their produce, are attacked and devoured by a great variety of insects, an
enormous number of new species of which will be found in our Encyclopaedia of Gardening.

We shall, however, advert to
those curious minute insects: Thrips Physiopis, fig. 158. A, B and C. It is a
spotted insect, which departs from its large form, and is
spring, and which, in their natural size (f), appear like short black lines. Nearly all fruit trees are liable
to considerable injury from different species of Coccus or cochinell insects. They are mostly so small
(fig. 972 a, d), that their form cannot be well distinguished without the aid of a magnifying glass; many of them resemble small scales or scabs fixed on the bark and shoots. One is entirely of a brown colour (Coccus persicorum a); when magnified (b) it somewhat resembles the tortoise beetle (Cassida L.), the legs and head being only discernible when the insect is turned on its back (c). Another (C. fol. quercus,
d, e, c) does much injury to the oak; while the C. figi attacks the twigs of the larch (g), and causes small round excrescences to appear; these are, however, very different from the gall apples of the oak (j) which are often found of a considerable size, and are produced by the Cynips quercus folii L. (k), or oak gall-fly, and always contain either the larva or imperfect insect. The weevils (Curculiónidae) form an exceedingly numerous family, subsisting principally upon fruit, seed, and grain. One of the largest found in this country is the nut-weevil (C. noænum, fig. 976c, c), the larva of which (a, d) are the maggots so frequently found in this fruit.

7681. The insects injurious to plantations are less numerous in this country than on the Continent, yet we have two species whose devastations of late years have caused much alarm and extensive injury. The pine plantations in various parts of Britain have suffered from the great saw-fly (Uroleucus gigas L.), the larva of which, feeding upon the heart of the tree, and boring it in all directions, soon destroys it. Another small insect of the beetle kind (Scolytus destructor F., fig. 973. d magnified) is equally deadly to the elm, and from being more common, and propagating very rapidly, is more to be dreaded. The sudden destruction of a large proportion of the elms in St. James's and Hyde Parks has recently called the attention of government to this beetle; and at the request of the noble rangers, Mr. Macleay undertook to investigate the evil: the result of his observations have been since published (Edinb. Phil. Journal, No. 21). It appears that the female (a) may be found upon the trunk of the elm from March to September; she first penetrates through the bark, and then proceeds to form a passage between that and the wood, depositing her eggs during her progress on each side; when these are exhausted, the parent dies, and is often found dead at the extremity of the passage (b) thus formed. When the eggs are hatched, the young larva immediately begin to feed by working nearly at right angles (c) from the path of the parent, each proceeding in a parallel direction and close to his neighbour; in this state they may be found in January. To stop this mischief as much as possible, Mr. Macleay recommends that the trees should be inspected twice a year; in summer, when the perfect insect is on the wing; and again in winter, when infected trees should be cut down and burned, or subjected by fumigation to such a degree of heat as may destroy the larva; or the bark may be covered with a mixture of tar and train oil, in March, to a certain height from the ground, applying this composition only to such trees as are still hopes of preserving.
PRACTICE OF AGRICULTURE. PART III.

Insects and Inocul. Insects, which, in general, grow in almost every plant, are the most universal devastators of the vegetable world; almost every plant has its peculiar species; their fecundity is so prodigious, that Reaumur has calculated that a single generation of Aphides may be the progenitor of 2,561,000,000 descendants; and it is supposed that in one year there may be twenty generations! Those which attack the different kinds of grain seldom multiply so fast as to be very injurious; but those peculiar to pulse increase rapidly, and take such possession, that the plants are greatly injured and frequently destroyed before the seeds are matured.

7603. These insects are equally injurious in their winged (fig. 579, magnified) and in their larval or worm-like state (fig. 574). The larva is a favourite food for carnivorous and other birds, who destroy numbers; they are likewise exposed to other deadly and cruel enemies; one of these is a small hymenopterous insect, which deposits its egg in the body; it is there hatched, and feeds upon the interior, in a short time the Aphid is killed, becomes hard, and, from being green, changes to a dark red colour. The artful destroyer, when he finds his victim dying, eats a hole through its body, and carries the Aphid, by that part, to a field of turnips. When the parasite has thus devoured the inside, and is ready to emerge as a perfect insect, he opens a passage for himself by cutting out a round hole in the side, leaving the head, like a doorknob on the doors, adhering to the body. But the most instructive and destructive foe to the plant-insect is the lady-bird or lady-cock (Coccinella, &c. fig. 571 a), which, in Europe, is a great enemy to these insects; and the haves or insects among them may be conceived, from the revolutions and of these pretty little creatures which are usually seen in years when the plant-house abounds; one or two, probably destroying tens of thousands of Aphides before he becomes a beetle. On this account the lady-bird is the greatest friend to the gardener and farmer; and could there be any method devised of increasing these useful insects as will, our flower-sign, gardens, fields, and hop plantations, would soon be cleared from the ravages of plant-insects. The larve of several bee-like flies (Nyrphus C. e.) are no less useful in this respect. Their form is very much resembling that of the honey, having no apparent head. Some species are green, with a white stripe down the middle; others brown, variegated with darker stripes. They are always found upon those plants most infested by Aphides, upon which they solely feed, for nourishment; hence they become most beneficial, and should on no account be destroyed. As palliative measures, the application of powdered quick-lime, the cutting down, or the destruction of the most infested shoots may be toppled off before the insects are greatly multiplied, repeating the same operation before the time that the winter snows of eggs are deposited. By the first and by the second, the following year's breed may, in a great measure, be destroyed. [Philos. Trans. 11. p. 114.]

7604. The wire-room is a name that has been given, without discrimination, to the larvae of grubs of various insects, totally different from each other: hence it is, that much confusion will be found respecting it in agricultural books. The true wire-grub is the grub of a small beetle (Elatler segetis Marsham), and it derives its name from its slender form and uncommon hardness. It lives in the larva state nearly five years; during which time it is supported by devouring the roots of wheat, rye, oats, and grass, which it attacks indiscriminately, and causes annually a large loss to corn fields; the same wire-grub, at last, abounds chiefly in newly-opened land, and is particularly destructive in gardens recently converted from pasture land. In the larva state it may be decoyed by offering it more tempting food, but no method has yet been devised for destroying the perfect insect.

7605. The grub is a general name for several larvae of crane flies (Tipuladae), called by the country people long-legs, or galler long-legs.

7606. One of the most destructive among these insects is the root-grub or Tipsula of the Tippula species. The larv is said, by some authors, merely to loosen the roots by boring among them; but others assert, that it likewise feeds upon the fibres. Howver this may be, the evil produced is evident; for in many parts of England it eats off a large proportion of the wheat crops, especially of those sown upon corn-fields. Reaumur informs us, that sometimes in France, particularly in the country near the Seine, the grass of a whole district has been so destroyed by it, as not to produce the food necessary for the sustenance of the cattle. No efficient remedy has yet been discovered for this evil; and Steckley suppresses, that the insect is not killed by lightning, or fire; and that it abounds in greater numbers than usual.

7607. There are several other species of a large size, as the Tippula crenata (fig. 573 c), and Tippula rivula (d), which, in a less degree, are also injurious to such lands as are moist and habitable.

7608. Another minute species is particularly destructive to corn, and is generally known as the wheat fly (Tippula tritici); its history and economy has been ably investigated by Mr. Marshan and Mr. Kirby. The injury first appears in the ear; the kernels growing among the straw, or husk, are found to contain an orange-coloured powder; in this are concealed very minute larvae (f), which, in many instances, are seen to be thick at one end, extending and contracting themselves at pleasure, and frequently jumping half an inch at one spring: they take their station in the longitudinal furrow of the grain, and by seeking its milky juice causes it to shrink up, and become what the farmers call powdered; the last worm when always appears the most infected. In the beginning of June the perfect insect (b) may be seen in innumerable multitudes, flying in the evening in all directions above the corn-fields; but during the day not one is to be perceived. The female lays her eggs (1) of a magnified form of a reddish tube, which secretes a very long and acute sting resembling a hair; but this can only be distinctly seen when the insect is magnified (b). The wheat-fly would soon become a formidable enemy to mankind, were it once exposed to an injurious food, scarcely larger than themselves; this is the Ichneumon Tipulae, the female of which carefully searches out the grubs of the wheat-fly, and deposits in each one of her eggs; these are hatched, and ultimately the larva devours the body which gave it life. One Ichneumon will thus cause the death of many dozens, and prevent the future multiplication of thousands. The only palliative that has been recommended for stopping the progress of this insect has originated in Mr. Kirby; this common wasp naturalist thinks much benefit would be derived by fumigating the corn with tobacco and sulphur, when the eggs are laid; this must be done as soon as the ear begins to shoot from the leaf sheaths. [Linna, Trans.]

SUBJECT. V. Insects injurious to Food, Clothing, &c.

7609. The manufactured produce of our fields and gardens, whether as food or clothing, is still exposed to the ravages of other tribes of insects, which take up their residence in them, and cause great injury. Among the insects that are injurious, or that have been naturalised in Britain, the principal are the cockroach, the house-cricket, and the bacon-grub.
The cock-roach, called by some the black beetle (Blitza orientalis, fig. 376, c), was originally imported from India, and is now naturalised in every temperate part of Europe. Like most of its tribe, it shuns the light, both natural and artificial. In the London house, particularly in the rooms on the ground-floor, it is very abundant, and indiscriminately devours food, meal, flour, and even clothes. As soon as light appears they all scamper off as fast as they can, and vanish in an instant. It is virtually to be killed in a much readier manner in pans of water, milk, and other fluids; it is said they will even attack stockings, or linen hung out to dry. They require great warmth, and are therefore mostly found in kitchens and backhouses. Another species is peculiar to pastures, which, in conjunction with the male cricket, feeds only upon roots: both these, however, are too local in this country to be very extensively injurious.

The bacon-grub (Dermestes lardarius L.) is sometimes as abundant in farm-houses as the cock-roach in those of London and other large towns; both insects devour every kind of food, and are often found drooping in pans of water, milk, and other fluids; they will even attack stockings, or linen hung out to dry.

The principal insects injurious to the agriculturist have now been enumerated: there are many others which feed upon cultivated vegetables and domestic stores, but in a less extensive degree. Let us not suppose, however, that these little animals have been created for the destruction of mankind; we have but taken a view of one side of the picture; the other would show us innumerable benefits, either immediate or remote, which we derive from this race of beings. The silkworm, the honey-bee, and the cochineal insect must not be forgotten; and myriads of others are created, whose sole occupation during life appears to be that of devouring and keeping within due limits those tribes that are injurious and hurtful to man.

SUBSEC. 5. Operations for subduing Insects.

The operations for destroying insects, or counteracting their injurious effects, are various, and in most cases must be regulated according to the species. These we have already pointed out in treating upon the insects themselves, or of the particular plants upon which they feed. It only remains to offer such general rules as are more or less applicable to all destructive insects; these are of three kinds, preventive, palliative, and efficacious.

The preventive operations are those of the best culture as relates to the choice of seed nor plant, soil, situation, treatment, and climate: the four first are under the control of man, and an attention to them will undoubtedly lessen the risk of injured crops, but as regards weather, neither his foresight nor care can avail anything.

The palliative operations are numerous; and such as are eminently successful may be considered as efficient; inasmuch as they are so frequently applied to a certain extent of insects, the species will still remain, although in such smaller numbers that its operations may escape notice. Most insects will be injured, and in part destroyed, by artificial bad weather, such as excessive waterings, stormy applications of water, and syringing with water; this will thus be bruised, and others that are shaken to the ground can be destroyed. Insects may be further injured by watering the plants upon which they feed, either with tobacco or lime-water, or by scattering upon the leaves powdered quick-lime, soot, ashes, barley awns, &c. The smell of the latter is particularly offensive to all insects, and the gentle fumes of tobacco, sulphur, urine, &c., are well known. Hot water may be applied with much advantage. Water heated to 120 or 120 degrees will not injure plants whose leaves are fully expanded, and it may be increased to 150 for such as are without leaves.

Insects may be destroyed in a much more effectual manner by enticement, or placing in their way other food as a trap. The late noble and generous Sir Joseph Banks has the merit of having recommended and made known this most efficient method. It simply consists in cutting slices of potatoes or turnips, sticking them upon skewers, and printing them near the seeds of the plants; the vermin will collect upon them during nights, and by examining them every morning, vast numbers may be destroyed; this plan has been very advantageously tried with the wire, and no doubt would be equally beneficial in clearing all crops that are attacked by underground feeders. Mr. Kirby says, "that it was very successfully practiced in 1815, by J. M. Reddall, Esq. of Barham Hall, near Ipswich, one of the most skilful agriculturists in Suffolk, to preserve some of his wheat-fields from the ravages of a small grey slug, which threatened to demolish the plant. Having heard that turnips had been used with success in the same way amongst the slugs from France, he caused a sufficient quantity to cross eight acres to be got together; and then, the tops being divided and the apples sliced, he directed the pieces to be laid separately, dressing two stitches with them, and omitting two alternately, till the whole field of eight acres was gone over. On the fol-
lowing morning he employed two women to examine and free from the slugs (which they did into a measure) the tops and slices; and when cleared, they were laid upon those stashes that had been omitted the day before. It was observed invariably, that in the stashes dressed with the turnips, no slugs were to be found upon the wheat, or crawling upon the land, though these were abundant upon the turnips. It might be seen in great numbers both on the wheat and on the land.

The quantity of slugs thus collected was near a bushel. Mr. Radwell is persuaded that by this plan, he saved his wheat from essential injury. (Kirby and Spencer, Int. to Entomology, i. p. 182 note.)

7709. The turnip net (fig. 977.) is an instrument invented by Mr. Paul of Starston in Norfolk. It is the most successful expedient that has yet been thought of for the capture and destruction of the turnip worm, called by farmers the black jack, and by hop-growers the fleas. It consists of two pieces of stout wood, the ends of which, at one extremity, are fixed into a handle in a forked direction: the other ends are left free, to be turned upward, after the part next the ground was smoothed smoothly and easily over the surface of the ground: towards this end, the sticks are connected by a cross-bar formed by a thin iron rod, that may be taken on and off at pleasure: these three bars constitute the frame work for supporting a long and ample bag, made of strong glazed calico. The method of using it is by the operator throwing it before him on the ground, over the tops of the turnips or other plants; by this means the insects that are upon the leaves fall into the bag, which may be occasionally shaken during the process, so as to bring them to the bottom (which is made narrow) where they will remain. Vast quantities of insects, which from their smallness and agility defy hand-picking, will thus be captured. The turnip net may be made either large or small; perhaps two feet and a half for the side sticks is the best length; it being obvious that the wider they are apart, the greater space will be brushed at once.

7710. The lime-duster (fig. 978.) is a recent invention by Mr. Samuel Curtis of Glazenwood, near Coggeshall, Essex, and has been used by him with great success in throwing pulverised quick-lime over the apples of hay and other plants infected by caterpillars or thrips. Containing many thousand fruit trees, and occupying fifty acres, had been for many years completely devoured of most of their foliage and young fruit in the spring months. Washing the stems and branches with lime and water as might have been expected would have been of no effect; the defects were found in the ladies of the turnips, feeding upon the young buds and leaves. The instrument in question consists of a canister twelve inches long, seven inches wide at its broadest, and four inches on its narrowest part. The top (a) is five inches and a half wide, is fitted with a cap (b), which is put on when the lime is to be thrown on low trees; but when high trees are to be operated upon, the cap is removed, and a pole of sufficient length to reach the height required is inserted into the handle. Quicklime pulverised and often sifted through a fine sieve is put into the canister, and shaken over the young foliage just as it was expanding. The time for doing this is in the dew of the morning, or whenever the leaves are damp; and if there should be a gentle breeze, sufficient to carry the dust on the surface of each tree, it is the more quickly performed. Under favourable circumstances of this nature, Mr. Curtis says, "I found that three men, provided with the powder in a large box on a light wheelbarrow, could dress from two to three thousand trees in a day: when the wind changed, I had the trees dressed on the other side. Although used ever so freely, no person need fear any injury, from the caustic quality of the lime, on the most delicate and fresh expanded foliage; it is only prejudicial to insects of all kinds, and to dead vegetable matter." (Hort. Trans. vol. vi. p. 2. page 124.) We know not whether the lime-duster has ever been tried upon hop plantations infected by the green fly or plant louse; but it appears to us equally well adapted to effect a great destruction among those insects.

7711. Grass of all descriptions may be infected by weevils, which are eaten by the grubs of other insects, should be spread in the sun, and frequently turned: the warmth will bring the animals out of the grain, and considerable numbers may be destroyed. It has been said that they may be kept away by strewing boughs of elder or branches of hawthorne among the grain, but this would not preserve this weed from destruction, as the apple worm is more injurious. The wire-worm is not addicted to this tribe, but is the larva of a small beetle already noticed.

7713. Catching the perfect insect is undoubtedly the most certain plan for preventing a return of the same injury the following year, for the death of one female will cut off a generation of a hundred larvae; but from the difficulty that attends an extensive adoption of this plan, it is not likely to be much attended to.

SECT. IV. Worm-like Animals injurious to Agriculture.

7714. Of worms (Urodes L.) generally so called, there are but few which may be considered as injurious to agriculture. The principal of these are the various species of slug (Arion F., Limax L.) and the large and small ear worm (Lunibrassus terricris L.), unless existing in great numbers, are not among injurious animals, notwithstanding the prejudices of farmers and gardeners against them. With-out worms the earth would soon become hard, cold, incapable of receiving moisture, or of giving nourishment to roots: they are, in fact, one of the best promoters of vegetable growth and of promoting the growth of roots in the soil beneath, and by mowing it above with their excrement, which is thrown up into mounds called worm casts. The wire-worm does not belong to this tribe, but is the larva of a small beetle already noticed.

7715. Worms of the slug kind are without shells. There are several species inhabiting Britain, all of which subsist on leaves, roots, and vegetables. The most common is the Limax agrestis (fig. 979. a'., of which there are several varieties in addition to the agriculturist and gardener; they devour the young shoots of turnips, wheat, and indeed all kinds of grain, frequently to a ruinous extent; they are also very injurious, and deposit small, round, of a semiellipsoid whiteness, and are deposited in the earth. The methods of destroying or eradicating the perfect animal have been already described.

7716. The shell slug (Testacea L.) is a native of Teneriffe, and has likewise been found in several parts of France and Spain; it has recently been discovered in some gardens near Bristol, by Mr. Miller, of that city. It is a highly curious animal, remarkable for feeding upon earth worms; and may, therefore, be beneficially introduced into such gardens as are stockressed by that otherwise
useful animal. It is readily distinguished from all other slugs in this country by having a thin oval shell (c), affixed to the hinder part of its body. Slugs in general are easily enticed by cabbage leaves, scattered near such garden vegetables as they appear to injure most.

7708. Snails, are slugs covered by a shell. The two species most peculiar to cultivated vegetables, are the garden snail (Helix aspera Gm.), and the variegated snail (Helix nemoralis, c); both these seek the same description of food, and are equally injurious, as slugs; and, like them, may be enticed by cabbage leaves and other juicy vegetable refuse.

PART IV.
STATISTICS OF BRITISH AGRICULTURE.

7709. After having considered agriculture as to its history, as to the scientific principles on which it is founded, and the application of these principles to the different branches of practice; it remains only to take a statistical survey and estimate of its present state and future progress in the British isles.

BOOK I.

OF THE PRESENT STATE OF AGRICULTURE IN THE BRITISH ISLES.

7710. Agriculturists may be arranged as operators, or serving agriculturists; dealers, or commercial agriculturists; counsellors; professors, or artists; and patrons.

Sect. I. Operators, or serving Agriculturists.

*7711. The lowest grade in the scale of this class is farm labourers, who may be either men, women, or children; and either local residents, periodical visitors for particular labours, as hay-making, reaping, &c., or itinerant workmen for taking jobs, as ditching, stocking, &c. None of this class of operators are supposed to have received any other professional instruction than what they have derived casually, or from observing others.

7712. Apprentices are little known in agriculture; but they occur sometimes, either as the children of other operators, whose parents bind them a certain number of years, during which they are to work for their food and clothes, and £1. or 10l. to be received at the end of the term according to conduct; or sons of richer persons, who pay a premium for the instruction to be received, and for board and lodging with the master. The former class of apprentices generally look forward to being ploughmen, shepherds, head ploughmen, or inferior bailiffs; the latter to being first bailiffs, stewards of estates, or to farming on their own account. Parish boys are sometimes bound apprentices of the first class, and various noblemen's sons from almost every kingdom of Europe have been included in the second.
7713. The term journeyman is as little known in agriculture as apprentice. Those who answer to that term are the professional operators of a farm, such as ploughmen, cattle herds, shepherds, and hedges. These rank decidedly above labourers of all work. A ploughman may not unaptly be considered as the rank of an apprentice till he can fear or set out ridges, and after he can do this as of the rank of journeyman till he can mix and sow. He may then be considered as the best pair of horses, and if twenty-five or thirty years of age, to enter into the marriage state.

7714. A hedger is a professional operator, who may be considered as ranking with a master ploughman. 111. He ploughs, cleans, picks, and hedges, cuts, lays, plashes, and other operations of vineyards, and to effect other operations with ligneous plants on the farm. In Berwickshire hedgers are generally very intelligent men, and keep the fences on the farms in the border counties in excellent order, and the hedges-row trees hambsonly pruned.

7715. A bailiff is an operator employed to prune trees and manage hedges, and is of the same rank and requires the same kind and degree of professional knowledge as the hedger. Generally he is more conversant with boring trees for the tanners, converting copsewood and measuring timber, than the more superficially engaged with vineyards than hedges.

7716. A head ploughman, on small farms, is to be considered as the bailiff in the absence of the master. He works the best pair of horses, and assists the master in stacking and sowing. On larger farms, where a regular bailiff is kept, there is also a head ploughman, who acts as substitute for the bailiff, in his temporary absence, for as far as laboring operations are carried on, and overseeing cattle, and particularly the stock, as he is in a better position to attend to the welfare of the breed.

7717. A farm bailiff is, or should be, a person of tolerable education, who understands accounts, measuring of work, land, and timber, and can draw up agreements for hiring servants. He should have practical knowledge of farm work, as well as of the management of the farm, from tending the stock, to stacking and sowing. When employed by a gentleman, or one who has no skill in farming, he should not be under twenty-five years of age; but a farmer's bailiff need not exceed twenty-one years, is to be considered as a sort of apprentice, and will be directed in all leading matters by his master.

7718. A bailiff and gardener, or gardener and graver, as they are called in some places, is a sort of hybrid upper servant, who seldom excels either as a farmer or a gardener, and is only fit for situations of limited extent, and an indifferent style of performance.

7719. The yeaster or head woodman is to the woods of an estate what the bailiff is to the farm lands in hand. He directs and superintends the woodmen and their labourers, in planting, rearing, and pruning plantations, and in the felling of timber or copse, barking charcoal making, and in short every thing connected with timber, trees, copse, or hedges.

7720. The head steward [Factor, Secr.; Factor, Fr.; Factor, Ger.; and Factor, Ital.,] is to a whole estate what a bailiff is to the demesne or a particular farm. His business is to control the managers of the lands in hand, as the forester, gardener, bailiff, &c.; to see that farmers fulfil the covenants of their leases; to attend to repairs, roads, public and parochial matters in behalf of the landlord; and generally to receive rents.

7721. Under stewards, or steward's bailiffs, as they are called, are assistants to the main steward, or have the care of detached estates, containing a few farms or woods.

7722. Deneme stewards are such as are kept chiefly for regulating the affairs of demesne lands; that is, lands surrounding the mansion in hand, or of an estate of small size, where all the lands are in hand, but where an extensive establishment of horses, servants, a large garden, &c. are kept up. Here the steward performs many of the duties of bailiff, for he has charge of the stables and game-keeper, and other domestic rural matters.

7723. Court farmes Hoyfencier, Ger.; Grangero de la corte, Span.; AGRICULTURISTS
7724. May be considered the highest step, the same honours of agricultural serv-
7725. Imitation agriculturists are of two kinds: such as take grounds for the culture of one or two crops of particular sorts of plants, as wood, flux, &c. (9864); and such as travel with a plough and pair, &c. to teach imitators to young farmers or their servants, a practice at one time carried on in Ireland under the patronage of the Dublin Society.

7726. Cottage farmers are such as possess a cottage and an acre or two of land, which they may either keep in aration or pasture; disposing of the corn, green crops, or dairy produce in various ways, according to the circumstances of the particular case.

7727. Poultry farmers, such as devote themselves chiefly to the breeding, rearing, and fattening of poultry, and the growing of feathers and quills.

7728. Garden farmers are such as possess lands near large towns or sea-ports, and grow the common garden vegetables, as peas, onions, cabbages, &c. for the market, or herbs for the distillers and druggists.

7729. Sod farmers. Small farmers who devote themselves chiefly to the growing of garden seeds for the market, or (if they are a pair) to the garden. They are generally in the northern and southern districts of England, and chiefly in Kent and Essex. (See Enlow. of Gard. 24 edit. 7850.)

7730. Orchard farmers are such as farm grass or arable orchards, sometimes joined to hop lands and garden farms; often with a small dairy; with rearing of poultry, rabbits, &c., and sometimes with the breeding of domestic fowls. The stock of these farmers is generally a little better than that of the ordinary farmers.

7731. Hop farmers, such as make hops a principal article of cultivation, to which are sometimes joined garden and orchard farming.

7732. Pastoral farmers, such as keep cows for selling their milk in an unmanufactured state. These farmers are of course limited to populous neighbourhoods. Cow-keepers differ from cow farmers, in having their establishments in towns, and in purchasing, not growing, their cow fodder.

7733. Dairy farmers, such as keep cows and manufacture their milk into butter or cheese. These are found chiefly in the most fat districts, as Cheshire, part of Lancashire, Leicestershire, &c.

7734. Graziers, farmers whose chief business consists in buying, feeding, and selling cattle and sheep. Their lands are chiefly in old pasturage, and they are more commonly feeders than breeders. The most extensive graziers are in Lincolnshire and Lincolnshire.

7735. Stock farmers, such as devote themselves to breeding and rearing different kinds of live stock, especially horses and cattle. They are almost common in Yorkshire.

7736. Market farmers, such as devote themselves to the raising of the sheep and cattle families. They are common in the border counties, in Wales, and in the Highlands.

7737. Hay farmers are confined to a small district round London; where they grow chiefly natural or meadow hay for the London reach and saddle horses, and for cow-keepers.
7739. Wood farmers, such as rent woodlands, to be periodically cut for fuel, bark, fence wood, charcoal, or other purposes.
7740. Quarry farmers, such as rent quarries of lime or other stone, gravel-pits, clay-fields, marl-pits, &c.
7741. Mine farmers, or master miners or mine-holders, such as rent coal-mines, or mines of iron, lead, or other metals.
7742. Salmon or river farmers, or fishery renters, such as rent rivers or ponds for the sake of their fish.

7743. Those farmers, who farm an estate of good land under one hundred acres are considered small farmers; under three hundred acres, middling farmers; above and under five hundred acres, large farmers; and exceeding that quantity, extensive farmers: a very proper title, for few arable lands can be profitably cultivated on a greater extent than three hundred acres, and those which exceed that quantity are generally breeding or other stock farmers, characterised by their profession.

7744. Gentlemen farmers, are professional farmers on a large scale, who do not associate with their neighbors, as farmers, except when they meddle with respect to the succeeding, their style of living the habits and manners of independent men or gentlemen. It is a character extremely liable to ridicule by the vulgar yeoman and purse proud farmer on the one hand, and those persons who are gentlemen by profession and men of family on the other.

7745. Yeomen farmers, small proprietors who farm their own lands, but yet aspire not to the manners and habits of gentlemen.

7746. Farming landlords, proprietors who farm their own lands on a large scale.

Sect. III. Agricultural Counsellors, Artists, or Professors.

7747. The land measurer is the lowest grade of agricultural artists: he is very often the village school-master, and is called in to measure work done by the job; as mowing, reaping, hedging, trenching, &c.
7748. The agricultural salamander is a person who attends at fairs, markets, &c, and acts as agent to buyers and sellers of corn and cattle. There are also salamanders purposely for hay and straw, others for green food, turnips, potatoes, &c.
7749. The appraiser, or valuer of farming stock, comes next in order. This professor values the live and dead stock, and crops, tillages, manures, &c, and sometimes also the remains of leases between landlord and tenant. This professor is generally employed to establish rent, or to effect other transactions, which he is authorised by the owner to do. Occasionally the appraiser is employed to value lands, but this is generally the business of the land-valuer.
7750. The land surveyor generally confines his avocations to the measuring and mapping of lands; or to their subdivision, or the arrangement of fences and other lines; but sometimes he joins the business of appraiser and valuer, and even timber-surveyor, as well as the business of the land-valuer.
7751. The timber surveyor and valuer confines himself in general to the measurement and valuation of fallen or standing timber; he also measures and estimates the value of bark, faggots, roots, charcoal, ashes, willows, hoops, and various other products of ligneous plants.
7752. The land valuer not only values the rental, but the price or fee-simple of lands, buildings, woods, quarries, and waters. He does not often meddle with metallic or saline mines; but he sometimes values fisheries, stone and lime quarries, brick-earth, gravel, chalk, &c. He is not a general knowledge of agriculture, but a very extensive acquaintance with the country in which the property lies, and great experience in business. There are local and general land-surveyors and land-valuers; the general profissors live in the capital cities or in the metropolis, and generally unite the business of land-agent.
7753. The land agent may or may not be a land-valuer, but at all events he should possess the knowledge of the valuer in an eminent degree. His business is to effect the transfer of property by purchase, sale, hiring, or letting; and also to collect rents, and often to relet farms, and effect other business belonging to the land-valuer. Land-agents are very frequently attorneys, who know little of agriculture; but who save their employers the trouble of employing both a land-steward of superior abilities, and a lawyer to draw up agreements and leases. It is the opinion of the best informed agriculturalists, that the employment of attorneys as land-stewards and agents has been one of the chief causes of the retardation of agriculture throughout Europe. Chateaubriand has clearly shown how this cause has operated in France and Italy; and Dr. Henderson, Arthur Young, Marshal, and various others, have deprecated its influence in Britain. The love of precedents, which this species of law proceeds from habit, has counteracted the tendency to change and amelioration.
7754. Of agricultural engineers, water-workers; the irrigator, for watering the surface of grass-lands; the root engineer, for laying out roads; the mineral surveyor, for searching for, measuring, mapping, and valuing mines and minerals; the coal viewer, for estimating the value of coal-works; the rural architect, for designing and superintending the execution of agricultural buildings; and the hydrographical and canal engineers, for canals, harbours, mills, and the greater water-works.
7755. The veterinary surgeon, or agricultural doctor, is to be considered as a rural professor; and as subordinate grades, may be enumerated the farrier, Ferrier, Fr.; Ferrajo, It. a smith, from ferrum, Lat. iron, covelech, and escastror or gilder.
7756. The agricultural draftsman, or artist by way of eminence, is employed in designing and painting live-stock, implements, plants, and cultivated scenery; the plans of buildings made by the architect, and new inventions in machinery and implements are drawn by the inventors, whether millwrights or agricultural mechanists.
7757. The agricultural author may be considered as the most universal kind of agricultural counsellor, since his province is to instruct, to execute the art, and comprehends times and practices past, present, and to come. The simplest variety of this species is the author of single papers in magazines, or the transactions of societies; the most extensive, he who embraces the whole of the subject; and the most valuable, he who communicates original information.
7758. The professor of agricultural science (Professeur d'Agriculture ou d'Economic Rural, Fr.; Hochlehrer von Ackerbau, or H. von Landwirtschaft, Ger. ; Profesor de Agricultura, Span.; and Professor d'Agriculture, Ital.), when appointed by a permanent or national institution, may be reckoned the highest grade of agricultural counsellor. He is a self-constituted man, like the professor; but constitutes himself the independent judges as capable of instructing the public. The first public professor of agriculture appointed in Britain was Dr. Coventry of the University of Edinburgh, about 1750; and in Ireland by Sir Humphry Davy, Lecturer on Agricultural Chemistry to the Board of Agriculture, 1807: both highly esteemed by agricultural cabinets as the natural complements of their other arts. There are agricultural professors in Dublin and Cork. In almost every University on the Continent there is an agricultural chair, and in some of the German and Russian Colleges there are chairs for gardening (Gärnerie), forest culture (Forstwesen), and rural architecture (Landbaumeisterschaft).

Sect. IV. Patrons of Agriculture.

7759. Every man being a consumer of some description of agricultural produce, may be considered a promoter of the art by causing a demand for its productions. The more valuable consumers are such as
live on the best bread, butcher's meat, fowls, and dairy products; and the greatest of all patrons, both of agriculture and gardening, are such rare specimens of agricultural benevolence, their farms, and, of course, their produce, are the best models of agricultural improvement. Amateur agriculturists, lovers of agriculture, promote the art by the example they set in its practice; and, of which, to a certain extent, they become purchasers, as of farming books, prints of cattle, implements, &c.

Sometimes, critical or skilful lovers of agriculture, promote the art in the same way as the amateur, but much more powerfully, in proportion as approbation founded on knowledge is value before that which arises chiefly from spontaneous affection. By the purchase of books, models, attendance at agricultural exhibitions, &c., the agriculturists encourage the amateurs. Sometimes, also, by their writings, of which Sir John Sinclair is an eminent example.

Employers of agriculturists, whether of the serving class, as bailiffs, stewards, &c., or of the order of professors of art, are obvious encouragers of the art. Amateur farmers are patrons on the same principle as employers; and sometimes, also, they effect improvements, or communicate valuable information to the public. Clinie, the late eminent surgeon, and the late physician, Dr. Farr, were eminent examples.

Improvements, suits, and manufacturers are conspicuous patrons. They render the art fashionable; and by the general attention so directed, and consequent occupation of many minds on the same subject, new ideas are elicited, and dormant talents called forth and employed. The names of Russel, Coke, Curwen, and Somerville stand in the front of those of this species of farmers, as of all other kinds. Noblewomen, and gentlemen improvers, whether by planting, building, road-making, establishing villages, canals, harbours, &c, are evidently greater patrons of agriculture than noblemen farmers, since their improvements affect society much more extensively than it is on the head of this species of farmer might be mentioned the late Duke of Bridgewater and the present Marquess of Stafford, and to these names might be added a number of others.

Different Kinds of Farms in Britain relatively to the different Classes of Society who are the Occupiers.

Cottage farms form the first link in the chain of temporary terestial possessions. They consist of one or more acres, or a bove a considerable extent, for the purpose of enabling the occupier to live a few: if any part of this and in the majority of cases the lad is either hired of some jobbing agriculturist, or done by the occupier himself or by two or more cottagers join together and form a team of their cows, with which, and implements borowed from the village carpenter or smith, they accomplish their labour.

Farms of working mechanics. These are larger than the former and are rented by country blacksmiths, &c., who often keep a horse or a pair of horses. Both the blacksmith and the farmer are very often violent to the occupiers, by driving off their attention from their principal source of income; though it must be confessed at the same time, that the idea of occupying land, and raising one's own corn, eggs, milk, butter, eggs, pulse, &c., is highly gratifying to a sort of sense of property, and has an air of independence and liberty, highly valued by men in general.

Farms of village tradesmen and shopkeepers. Many of these men, such as bakers, butchers, grocers, &c., keep a horse at any rate; by renting a few acres they are able to keep another, and add a considerable income of this nature to their retail stock. The idea of having a healthy recreation, and agreeable variety of occupation; and if this recreation does not interfere with main purp- suits, there is a gain of health and respectability.

Farms occupied with a view to profit by town and city tradesmen. These are on a larger scale than the last, and held by stable keepers, cow keepers, butchers, corn dealers, &c. They are often of considerable size, mostly under grass, and managed by bailiffs. Arable farms in such hands are rarely well managed, as every thing is made to depend on chance; but as less skill and vigilance is required in managing grass-lands, hay or pasture farms of this description are generally well managed, and consequently productive. They are seldom, however, profitable, and it is only because the renter reaps the double profit of grower and consumer, has some enjoyment in the idea of thing, and some increase of health from the exercise of the trade, that he visits it, that he finds it suitable to continue in the same branch of business, which has an air of independence and liberty, highly valued by men in general.

Farms occupied by city tradesmen for recreative enjoyment. These are of various descriptions, and generally managed by bailiffs. They may be considered as affording compensation only by the amuse- ment, exercise, and health which they afford, and the interest in country matters which they excite. Many of these farms are rented to men almost at rates which are much more remunerative than with the greatest industry and frugality, often joined to skill and ingenuity. When the farm promises well the tradesman is sometimes tempted to sell his trade and turn farmer for good (as it is called, i.e. he rents or buys a farm for the larger part of his income), and then he finds it suitable to continue in the same branch of business, which has an air of independence and liberty, highly valued by men in general.

Farms attached to the villas and country houses of wealthy citizens. On these the wealthy citizen plays at agriculture, aided by a skilful manager or bailiff. Immense sums of money are thus expended in the neighbourhood of large towns; many ingenious practices are displayed; and nothing in the way of profit is ever expected to be gained, yet on the whole an attention to agriculture is excited in the minds of wealthy commercialists, who buy books on the subject, procure bailiffs, approved implements and breeds of stock, and thus give encouragement to these and other productions connected with the subject. The practice of farming for the last twenty years round has been, as far as possible, a careful and skilful management, and the results are uniform, and very satisfactory, as well as highly gratifying to the farmer himself, and those who have other investments than his farm. The farming for the last twenty years round has been, as far as possible, a careful and skilful management, and the results are uniform, and very satisfactory, as well as highly gratifying to the farmer himself, and those who have other investments than his farm. The farming for the last twenty years round has been, as far as possible, a careful and skilful management, and the results are uniform, and very satisfactory.
milk, dairying, garden crops, hops, orchard crops, grazing, breeding, hay, corn, wood, minerals, as stone quarries, &c., or to fisheries. At the origin of what we now call farming, or when the hirer of land by cultivators succeeded to cultivating, for the landlords, or in partnership with the landlords, as is still the case, in England, large farms would of course be small, and farmers men of scarcely any capital or consideration in society. Just emancipated from a state of bondage and vilainage, the new-created independent tenant could not easily throw off the chains which formerly shackled his mind and prevented it from reflection, and he could have little or no property when he had no means of acquiring it but by plunder, or preserving it but by concealment. Hence the first tenants were assisted by their landlords; and one remnant of this practice, that of allowing farmers to have a year's rent always in hand, or, in other words, to demand the rent till the end of the whole year after it is due, still exists in some parts of Scotland, Ireland. In process of time, however, and from various direct and indirect causes, farmers at length acquired some degree of capital and respectability; and as they naturally thought of employing the serf, of course farms began to be enlarged to afford scope, and leasing was granted to afford security. This practice has been going on in almost certain for more than two centuries past, and receives a fresh impulse whenever the prices of grain rise high, and continue so for some time. At no period have they been so high as about the commencement of the present century, and during no period have the riches and properties of the farmers so much increased. Much of the great and political changes, however, have proceeded singularly disastrous to farmers; and till the corn laws are either obiterated, or regulated on some permanent and more moderate principle, agriculture and its practisers of every description will remain liable to the extremes of profitable occupation and ruin.

Chap. III.

Topographical Survey of the British Isles in respect to Agriculture.

7774. The British Isles, as we have already observed (1850.), are, in their present state, naturally and politically more favourable to the practice of the agriculture of ale, butter-meat, and wheat, than any other country in the world. They have the advantages both of climate, and inland water, on four sides, matters important; but, notwithstanding, there is no country in the world where farmers or proprietors are so respectable a class of men, and where such excellent corn, herbages, roots, and hay, either raw, or in their manufactured state of bread, ale, and butter-meat, are brought to market. 7775. Topographical Agriculture in each of the different counties of the United Kingdom is taken from the Surveys published under the authority of the Board of Agriculture, or the Dublin Society; from Marshall's remarks on these surveys, and his other writings; and, in some cases, from our own observations, having visited the counties, and inquired into the effects of the various political and commercial changes that have taken place in these countries, in the last sixty years. The richest grass lands are in the valleys of the great rivers, as the Severn, Trent, and Thames. The richest arable lands, in Worcestershire, Warwickshire, and in part of various other counties; and the best farming, in the county of Cumberland. The greatest variety of farming may be seen in the counties round London, and the greatest sauceness, regularity, order, science, success, and the wealthiest farmers in Northumberland and the county of Durham. The geology and minerals of the kingdom are most ably indicated in Smith's Geological Map of England, Wales, and part of Scotland, 1815; Smith's County Geological Maps, 1819 to 1824, and Smith's Geological Table of British Organised Fossils, 1819. These works are of the greatest importance to landed proprietors.

7776. The surface of England is estimated at from thirty-two to thirty-six millions of acres, with the exception of some mountains, a great part of Cumberland, and the northwestern districts, where the surface is more irregular than elsewhere, in many parts, or cultivated, and nowhere more capable of cultivation; in most places varied, gently and beautifully in some districts, and abrupt and grander in scale to others. The most high and mountainous districts are those of the north, and the most level those of the east. The most humid climaxes are those of the towns, hills, and coasts, especially those of the south-east, &c., as Norfolk and Suffolk. The richest grass lands are in the valleys of the great rivers, as the Severn, Trent, and Thames. The richest arable lands, in Worcestershire, Warwickshire, and in part of various other counties; and the best farming, in the county of Cumberland. The greatest variety of farming may be seen in the counties round London, and the greatest sauceness, regularity, order, science, success, and the wealthiest farmers in Northumberland and the county of Durham. The geology and minerals of the kingdom are most ably indicated in Smith's Geological Map of England, Wales, and part of Scotland, 1815; Smith's County Geological Maps, 1819 to 1824, and Smith's Geological Table of British Organised Fossils, 1819. These works are of the greatest importance to landed proprietors.

MIDDLESEX is part of the north side of a vale watered by the Thames, and contains 192,000 acres, exhibiting a great variety of agriculture. (Middleton's Survey, 1816. Marsh's Review, 1818. Edin. Gaz., 1827.)

1. Geographical State and Circumstances.

Climate. Healthy; warmer near London, from the fires kept there, which consume 30,000,000 of children of cows annually; stationary wintry from the S. W. and E. E., those from the S. W. breeze 6-10ths of the years, E. E. 3-12ths. Greatest falls of rain from a few points. W. S. and N. are of the longer continuance when the wind has passed through the valley of the Thames. In spring, frost in the hollows, when none on the hills, thermometer has been as high as 85°, and as low as 6° below zero.

Soil. By long continued mowing, the surface soil is almost everywhere level, about six feet thick, the lower portion of which is chalky, the upper part of clay, and in some parts of the Middlesex Hills, Chalk. London clay, from Hamstead to Cockfosters; sandy loam, from Hendon to Hounslow; from Hounslow to Uxbridge. Sands, from Uxbridge to Ealing, from Ealing to Acton, and from Acton to London. From Pinner, Harrow, to Staines; breccia between Sevenoaks and Tunbridge. Clay between Whitecliff Common and Horsham. Clayey ground about Hounslow and Highwood Hill; peat from Rickmansworth to Staines, on a substratum of the gravel of thins. Marsh land or rich fens deposited from still water in the Isle of Dogs, and the Lee and Cow. Swamps, gently waving; highest towards the north, Hampstead 80 feet above the level of the sea. One mile from London on the Richmond Road, the surface of approach of 1000 acres is levelled at an average five feet from the brink earth dug out, a high of ordinary quality has produced 4000. per acre and the nearest, for marble or white bricks, 50,000. per acre. Brick earth formerly 1000; now 500. per acre. An acre at four feet deep yields four millions of bricks.

Mineral water. 1. Cultivated surface. 2. Gravel of Hills, 5 or 10 feet in thickness. 3. Clay or clay, 200 or 200 feet in depth. 4. Marine gravel, 3 or 4 feet in depth. 5. Loess and gravel, and water, the latter arising from such quantities as to prevent digging deeper. Water. Abundant and excellent. 

The Thames, from Oxford to Maidstone, is twenty-one miles in length, and rises on ten miles; from Maidstone to Cheverton Bridge, 19 feet in feet; thence to Merstham, 13 feet; thence to Godalming, 10 feet per mile; from London the fall diminishes till it is lost in the sea. Tide flows twenty-two miles above the Thames; spring water found at various depths, from 5 to 500 feet; the latter, the depth of the Thames.

Mineral waters at East Acton, Hampstead, and Bagswoth. Jet, chalcedy of little use. Fish. English oradage, Scotch, salmon, tench, barbel, roach, dace, chub, brent, gudgeon, ruff, bleak, eel, smelts, and lam. 

AC 3
2. State of Property.

Property and agriicultural Improvement. Generally under the care of artisans, and badly managed.

There is much freehold, considerable extent of copyhold, some church, college, and corporation land.

Kinds of houses. Numerous, splendid, commodious.

Farm-houses, offices, stables. Oldest built with timber fath and thatched; modern with brick and tiled.

Churches, Town Houses, Chiswick, W. Kensington, and Pic- worth, models of their kind. Very few buildings required on boy farms.

Collas, brick and tile, and generally in villages; formerly with the common, now done away by enclosures.

Size of farms. Generally small compared with other coun-

tries; in Kent, 50 acres, from $500 to $600 a year

rented at from 1800 to 2000, each.

Many of 200 acres; average of about 50 acres.

3. Amateur farmers, who have left other pursuits. 4. Com-

mercial or professional farmers, equal in number to half the others.

5. Rural artificers. Had: impossible to get any agricultural implement or machine made a good principle by the country artificers; but able mechanics in London; Cotton and Hallen, Wykes and Phillips, Meden, and especially Weir, a North

umberland man, and practically acquainted with agriculture.

6. Expenses. Generally small, sometimes a small part in bounty and rent at fixed prices. Yards from 100 to 140 per acre, or higher for nurseries.

Tides in many places taken in, some compounded for annually, or for a fixed period.

7. Incomes for their relief, average 5s. 6d. per acre.

Leases, general. Often for fourteen and twenty-one years, Prod. for fifteen years "a composition of obsolete uninhabitable

8. Excess. Expenses on entering a farm, greater than on leaving; but farmers and landowners are made more subs-

ordinate to the farmer. The increase of canal, and the pro-

gress of manufactures and improvements on railroads, is rapidly removing distant and near towns and farmers' hands.

All bad; plough barbarous; threshing mills rare.

10. Easings.

Now mostly enclosed. Nineteen thousands enclosed from 1700 to 1800 containing 20,000 acres and upwards. Old fences of a mile wide of wattle and lath are neglected, and ruinous. Good fences of wattle and lath are of no value to farmers, and are neglected.

12. Land.

Newly enclosed. Nineteen thousands enclosed from 1700 to 1800 containing 20,000 acres and upwards. Old fences of a mile wide of wattle and lath are neglected, and ruinous. Good fences of wattle and lath are of no value to farmers, and are neglected.

Climate. Healthy winds S.W. and W. seldom blow from sea. Spring between S. and N. for a few days. East winds in spring, and then weather cold, raw, and dreary. Most

rain falls when the wind is N.W. or S.

Highways. Good; roads well kept. N. and H. Dist. in this

AGRICULTURE OF SUSSEX.

The county of Sussex produces a large variety of agricultural produce, including wheat, barley, potatoes, and hops. The fertility of the soil is due to the Wealden clay and chalk, which provide ideal growing conditions for many crops. The county is also known for its livestock, particularly sheep, and for its dairy industry.

Climate. The climate in West Sussex is generally mild and temperate, with significant rainfall, particularly in the western parts.

Soil. The county contains several soil types, including chalk, clay, sand, and loam, which support a variety of crops and livestock.

Crops. The main crops include wheat, barley, oats, and potatoes, with hops being a significant local crop.

Livestock. Sheep farming is a major activity, with various breeds such as Dorset and Southdown. Cattle, particularly dairy cows, are also common.

Forestry. The county contains significant areas of woodland, providing timber and other products.

Fisheries. The South Coast offers excellent fishing opportunities, with a variety of fish species.

Tourism. The picturesque scenery and historic towns attract many tourists, contributing to the county's economy.

2. Extensive rural areas.

The county's agricultural landscape is characterized by extensive fields and farmland, with a network of lanes and tracks connecting the various estates and farms.

3. Pasture Land.

Pasture land is a significant aspect of Sussex's agricultural heritage, providing feed for livestock such as sheep and cattle.

4. Improvements.

Improvements to farm buildings, water supply, and drainage have significantly increased agricultural productivity in the county.

5. Woodland.

Forestry is an important aspect of Sussex's landscape, providing timber, recreation, and habitat for wildlife.

The county's natural beauty and wildlife conservation efforts are well recognized, with designated areas of Outstanding Natural Beauty.

7. Rural Economy.

The agricultural economy is supported by a variety of industries, including food processing, retail, and tourism.

8. Farming.

Farmers in Sussex have adopted modern farming practices, including the use of precision agriculture technology.

9. Harvest.

The harvest season is a time of celebration, with various local festivals and events highlighting the county's agricultural heritage.

10. Agriculture.

Agriculture remains a vital part of Sussex's economy, with a focus on sustainability and innovation.
wheels 100 acres. Note on the Down 1879 to 1900 acres. 
Tithes taken in in many places, in others commuted for.
Poor's rates high.

Implements.
Plough with two wheels, large and singularly clumsy. The 
Reapers, however, were introduced, and deemed a real improve-
ment. Several excellent new implements introduced by the
abolition already mentioned.

County enclosed from earliest antiquity; fields small, 
being meadow, park and broad. White thorn fences at (oval 
wood, by the Duke of Richmond, framed in a masterly man-
ner; being like walls, or rather rugged manes of verdure rising 
fiercely from the ground.

1. Arable Land.
Four to five horses to a plough with a plowman and 
driver; plough from one half to three quarters of an acre a 
day; following generally on the stony soil. Rotation bad,
hence no crop rotation; where there is grass it is kept. 
County enclosed, from the earliest times of history, by the 
sandy lands; thistles by flail, and generally cleaned with a 
shovelled hoe and horse-drawn harrows and winnowing machines.
Outs a great deal cultivated on the wees. Few man cultivated 
rough land and bare land.

KENT. The root of the rhubarb, after growth of seven or eight 
years, is laid up, washed, dried in the sun, and then cut in slices and 
dried on the hot-house floor. (616.) Incisions are made in the poppy 
head, and the exuded juice, when dry, dried off into a 
crushed horn, to be used for the manufacture of opium and 
other excitants. 

2. Orchards.
Some considerable orchards, and elder made. One or two 
figured as in the fruit gardens. (See Essay, of Gard. 
Society.)

3. Plants and Plantations. 175,600 acres.
County celebrated from the remotest antiquity for the growth 
of its timber, especially oak. County at the contest one 
conquered by the French in 1878 from the French to the 
Inwood, cut at twelve years, for hoops and hopp-ales. 
Best profit usually wounded. Finest oak timber at 
Petworth.

Considerable extent to the north of the county. Some 
hundreds of acres improved by E. of Egremont answer well.

5. Forestry.
E. of Egremont sent for Elsham to find water to fill a 
lake. Undertook to do so; but all his trials and predictions 
of the result were found to be false. All of the land on which he cause

7790. KENT (Cant or Angle) forms the south-east corner of the kingdom, and extends over 500,000 
acres. It is diversified by chalky eminences in some places, low marshy grounds on the Thames and part 
of the sea-coast, and an inland, flat, and woody tract bordering on Sussex, called the Weald, or wood 
(544.) It is one of the most cultivated counties in England, 
and one of the richest in the kingdom. Its soil is of divers kinds, as it has, with the exception of the Downs near Dover, a more garden-like appearance than any county in 
Britain. Its agriculture is various; and it is celebrated for the culture of hops, fruits, barley, and various 

1. Geographical State and Circumstances.
Tracts. Subject to cold winds; the prevailing are the N. and 
S. Tracts. This county, winter, autumn, and spring, are 
twelve inches of ice, and the destruction of farms. Milder 
in N. and S. parts of the country. In Kent and Sussex 
early harvest, common July 21st, on the 1st August.

Soil. That of Thanet. Rich on rock chalk; of Kent 
very various; chalk, loam, strong, mellow, and mellow, mellow, 
clay, gravel, sand. Isle of Sheppey strong still clay; 
White sandy till. Our country is formed from chalk rock 
prevails; Weald chiefly clay, but mellow, sand, and gravel in 
Inwood. Romney Marsh settlement of the sea; a soft and 
clay.

Gently varied hills of chalk; Downs not so high as those of 
Sussex. 

Bridges. Numerous chnall bridges, at Tunbridge Wells 
the chief.

2. State of Property.
Supply of resources for a population of the increase: 90000 
freeholders, and a good deal of church land; colleges 
and monasteries, and military prelates.

Thirty or thirty-five noblemen's seats, and many seats of 
gentlemen in the country. Modern architecture, modern 
built houses; old sites of oak and chestnut, and ill 
converted. Many houses in the county are in general 
comfortable, built with bricks and tile.

Wheat, barley, rye, oats and peas are grown universally on 
poor lands; many farms from ten to fourteen acres each, few exceed 200 acres, some (not) to 1 acre. 
Small farmers are numerous. Crops are generally good. 
Grains are in general comfortable, built with bricks and tile.

5. Mode of Occupation.
Some in corn, some in pasture, some in fish. Much 
merchandised by the sea. Kentish ploughmen employed in 
the 

No common-field lands but some common; fences well 
and broad, with hurdles and hedges. Every farm, from five 
to eight or ten feet wide, and from three to five feet deep in the bank. 
Trees of oak, ash, beech and maple; also hedges of 
Romney Marsh. Neither fences, drains, nor water furrows 

cited in Thanet, where corn is grown, and often, for 
reasons in succession, the same crop.

6. Arable Lands.
Wheat and oats, from five to seven inches deep. Follows 
always on poor lands. Rotations good. Fees of various 
kinds for podding are shown from the middle of the year 
to the end of the year. The yield is very good. There 
are 200,000 acres devoted to the most profitable. 
Trekkens and seed; rich; much cultivated in the 

North, and second in the south. The town of London 
seed town in March, and crop seldom fit to reap before 
February, and are reaped after Christmas. Rates at 

the height of all kinds; raising any injury from wet weather; requires much rain to rot the 

to a dry place. Seed must; produce from eight to twenty 
four bushels per acre. Spring ploughing is in March. 
when in blossom the male plants (it being a dioecious plant) 
are used in the country. The crop is generally good, 

ground on the field; produce, to five to five quarters per acre. 
Romney 

marsh is the finest. Salts are used in the country, and 

London, and sometimes in stocks or barns for several 
years of warmth. This is the method of drying, and 

good and lowly but generally bought by speculation, who supply the 

dujures with a great deal of silk. Malvern formerly made 

vated in the eastern part of the county, now given up; first cultivated on a large scale near Feversham.

8. Hay chiefly produced in the marches and the weald; pastures for dairying on every farm; but no dairy management, except in the county; lands in Kent are changed from grass to arable, or the contrary. Hay making boldly conducted in most parts of the county, owing to the great demand for it. In Thanet and East Kent long sheep and cattle brought in and put on the marches and meadows till fit for the butcher.

9. Gardens and Orchards.

Near all the great towns a considerable portion of land devoted to the cultivation of vegetables, and at Greenhithe and Gravesend and are whole fields of asparagus, onions, cauliflowers, &.; at Maidstone, many fields of onions and other vegetables; at Canterbury, the strawberry culture is remarkable; in Thanet and East Kent many acres of strawberries are raised; apples, cherries, and filberts, raised among hops, the culture which causes the farmers to grow with great luxuriance; common practice to plant 800 hops per acre, 200 filberts, and forty apple and cherry trees per acre; the hops stand twenty years, filberts thirty, and the apples and cherries an unknown length of time. Sometimes apples and cherries in alternate rows with rows of filberts; if filberts also raised among hops without any other trees; trees planted in holes two feet apart, and two spits deep; pieces of wood, staked and their stems brushed over with lime and rose water, which is said to make them grow exceedingly. The golden reinette apple and black heart cherries, when a few years old, are found to grow and die; yet many old trees in full vigour; cherries do best with land laid down; filberts also do on few soils; best cider maker Stone of Maidstone, mixes all sorts of apples; senator golden pippin makes good cider alone; no occasion to watch the fermentation of cider in order to rack it off at any particular time, as alleged in Herefordshire: eating apples sent to London by the dozens, and to those of Kent by Gravesend, the cod vessels. Fruit orchards considered the most valuable estates. Trees from 8 to 10 per pound on account of their size and by a deep soil, and bear well for thirty years; filberts a story, shorthorn, sandy loam, rather inferior in soil and rich soil; principal hop grounds about Canterbury and Maidstone, on deep rich loam with a soil of loamy brick earth; production of fruit in a good county, per acre, average seven cwt.

Principal produce hop poles, flax; husbandry wood, and some little for the dock yards; few artificial plantations.

11. Improvements.

Open drains made between flat ridges by deepening the furrows of various crops, and bushwood drains in use; chalk will answer when before the reach of frost; sea beach and refuse bricks also very good; some built on a better plan (fig. 981.) by the Duke of Buckingham, with a garden of one fourth of an acre to each. Joseph French, in an advertisement in The Messenger, asking labour dear, and servants difficult to be got, took the plan of fixing by building them cottages and attaching gardens.

4. Occupation.

Some of the largest farms in the kingdom; so early as 1676 Arthur Young estimated the value of the lordships of Brabourn and Daylings, in 1100 acres, Lord Petre 2000. Many f.manors receive men of information, ingenuity, and exertion. Tithe average £ 60 to £ 70 per acre, when compensation for canals, railways, and roads is considered. In every parish held on running leases, terminable or renewable every seven years. The relief of leases increasing.

5. Implements.

Exceplough, a large widows implement, with a great variety of other ploughing implements, all built composed with the Rotherham plough and Northumberland plough. An iron road ploughing engine, of which the ancient of the Duchess of Devonshire's establishment, is attached, delineated in the report, but no reason given for the shape. Many cultivators, smallholders, and small farmers, using the Boston plough, the best and most approved implements introduced by Western, English workmen, and the whole improved implements introduced by Western, English workmen, and the whole.

Exceplough, a large widows implement, with a great variety of other ploughing implements, all built composed with the Rotherham plough and Northumberland plough. An iron road ploughing engine, of which the ancient of the Duchess of Devonshire's establishment, is attached, delineated in the report, but no reason given for the shape. Many cultivators, smallholders, and small farmers, using the Boston plough, the best and most approved implements introduced by Western, English workmen, and the whole improved implements introduced by Western, English workmen.

7. Livestock.

Cultivated better than nine in ten of the other counties; plough with two horses or three horses alone, without a drier, follows upcrops; sowings of turnips, and other crops, very good; good small horses; graveyards; and large horses, very good; some built on a better plan (fig. 981.) by the Duke of Buckingham, with a garden of one fourth of an acre to each. Joseph French, in an advertisement in The Messenger, asking labour dear, and servants difficult to be got, took the plan of fixing by building them cottages and attaching gardens.

Extensive marshes and salt-lands (or salt-leaks). Some cherry orchards at Burnham; many cottages without gardens.

9. Gardens and Orchards.

Some cherry orchards at Burnham; many cottages without gardens.

1139

Fifty thousand acres, chiefly natural and ornamental scenery. 

Hartfield, Salisbury, a brickyard (partly also in Buck's, Gorhambury, Hockley, the Ho, the Grove, Gathorne, Ware Park, &c. noble mansions. Hereon's farm yard, Gathorne, North Mins, house of the county. Impeccable forms at North Mins and Hedfordton. Gritter to the acres of farm buildings at Blandford, and vert in acres. The convenience of giving hay, water, and oil-seed. Cottages seldom with land about them. A nobleable house at Hendfordon, a cumbrous expensive affair of which plans sections, &c. are given in the county.

12. Occupations.

Farms small, largest 500 acres; many of the very small farms in the twentieth. At one time of Oliver Cromwell's depth, of ploughing generally four or five inches deep. Green, who has written a tract on managing his land, without naked falls, ploughs and fertilizes the land. A good many of the old-fashioned farmers are subject to the Marches, Salisbury farms 50 acres, and has made many curious experiments; a prejudice against leases. In this case, a small town. In the time of Oliver Cromwell's depth, of ploughing generally four or five inches deep. Green, who has written a tract on managing his land, without naked falls, ploughs and fertilizes the land. A good many of the old-fashioned farmers are subject to the Marches, Salisbury farms 50 acres, and has made many curious experiments; a prejudice against leases.

5. Arable Land.

The corn crops with Cocke's drill practised in various places. Watercress for the London market, cultivated in the steeplecots. Many acres for forge at Ashtead and Grove. Grazing quantity small, and chiefly a narrow margin near Barnet, on which hay is grown for the London market; some good meadows on the Scott.

6. Apples.

Apples and cherries abound in the S.W. corner of the county, from the end of May to the end of July. In ten years after planting, cherry trees begin to bear; produce till the twentieth year, six dozen pounds; when full grown, fifty dozen pounds; price, ten-pence to three shillings a dozen. Carrots, and small black, the favourite sorts. Renishall will not thrive here. Some of the apples for cider; orchards kept in grass, but not moved.

7. Woods.

The canoe kind abound in the northern and many parts of the county. produce faggot wood and hurdles; cut at twelve years; black willow, ash, and holly, cut for hurdles; elder bought by turners and pattern-makers. Fine woods, natural hedgerows, at which one of the earl of Cranbrook had a most extensive forest. A superb oak at Pasham Park, Earl of Chichester's seventeenth-century oak. A magnificent oak in 1791; on a soil gravelly above, but, doubtless, clay below. A chair of pines at Loughborough, belonging to a society of deacon, many immense pollards; and, on the whole, one of the most fine of the kind near Barnet.

The best beeches at Ashtead and Hookwood. Beech trees exceed there; also cedars and the oak, ash, larch, spruce, and common pine excellent. Beech sold for turkeys, chair matrices, and for barrel staves.
11. Improvements.

1. Undertaking clay by numerous parallel cuts filled with straw, wood, or some general manuring with farmyard manure; much brought from London of every sort; bones, soap, sheep troughs, sods, eyeballs, dyes, leather, feathers, tallow, manure, horse spavin, ferr)}

2. Prefers to instructions, also performed also marketable. Grey works suitable on horses, four to a team. Hon. G. Villiers proposed the Glamorganais work for corn; and thins, stall-fed

7753. BUCKINGHAMSHIRE. 48.20 square acres of hilly surface, and chiefly of clayey or loamy soil; a considerable part chalky, and the agriculture nearly equally in summer between a deep ploughed

(Survey by St John Priest, Secretary to the Norfolk Agricultural Society, 1810. Malcolm's Survey, 179.)

4. Occupations.

5. Implements.

7. Arable Land.

8. Grass.

II. Improvements.

1. Draining much wanted: well performed on some bogs on the Duke of Buckingham's estates by diggings, as showing in the bottom to the spring was tapped, and then leading it off in an underground passage till it is used for drying and furnishes a universal use for bringing grass land to tillage; chalk much used as a manure, slate or seventy loads per acre, once in two or three years, or forty once in twelve years; allowed to lie on the surface at least before being ploughed in; only one instance of irrigation water, which is at Cheylesmore, by a tenant of the Duke of Buckingham.

II. Live Stock.

1. Cattle kept chiefly for beef and butter, seldom for cheese or wool; Hereford, Shorthorn and some Norfolk cows for the dairy; some for the long horned Lancaster, and others the Suffolk; men, after being kept a few years, are sold to the London cow-keepers; men are generally the milkers; only one instance found of women performing that occupation. Exit of Bridgewater keeps eight teams of Welsh, one of Sussex, and one of Durham oxen, and 200, as made; these kept dairy water fed on straw, hay, and oil-cake, little hayage or roots in winter; milk

most common rotation fallow, wheat, beans: chief grains, wheat and barley; beans drilled and hand-hoed: some turnips on the light lands.

12. Live Stock.

13. Rural Economy.

Ploughmen generally hired by the year.

11. Improvements.

1. Undertaking clay by numerous parallel cuts filled with straw, wood, or some general manuring with farmyard manure; much brought from London of every sort; bones, soap, sheep troughs, sods, eyeballs, dyes, leather, feathers, tallow, manure, horse spavin, ferr)
generally kept in flat vessels of lead; some wooden trays, covered with glass, were skinned every twelve hours; in some few places three times a day; cream from first two skimmings kept by itself; the third skimming makes what is called altar-butter; skimming oil, if in fair, a foot in diameter, with holes in it, and a handle upon the top of it; butter made twice a week, in charge of the barrel kind, usually turned by a horse; time allowed for the butter to come, an hour and a half; butter made up in tumps of two pounds each, and sent to London in square flat baskets, eleven inches deep, holding from thirty-six to forty pounds. They have each on three of their sides three marks, the number of pounds the basket holds; a letter, denoting the farmer's name from whom it is received, and the name and residence of the carriers. The bakers and butter sellers both are the property of the carrier; all that the farmer has to do is to carry his butter to the nearest point where the carrier passes, and to make his agreement with his butter-factor in London, and receive money, or otherwise, the payment. Quantity of butter made, six pounds per cow per week, at an average, when in good keep, and not poorly dry. Caves generally, sold to suckles; a few sucked in the county, and a few brought up as stock.

Shops. Culture directed to the fattening of lambs, and the breeds preferred are the Dorset, and next the Gloucester and Berkshire.

Horses generally sotted; five or six put to a plough in many places, and never less than three. A team of ass's kept by the Duke of Buckingham for the use of his garden; many used at the potteries at Amersham.

Hogs, an important article on account of the milk from the dairies; bred the Berkshire, and next, the Chinese and Suffolk.

Wells, a material article at Aylesbury and places adjacent; bred white, and of an early nature. They are bred and brought from the same farms; and sent to London to the weekly carriers. One poor man had before his door a small pit of water, and a well of iron, and one well, made of lead; at two corners of this pit are places of shelter for the ducks, which, to the point of straw: at night the ducks are taken into a house. In order to get the ducks sweeping to this man (the only room he had to live in) were on the 11th of January, 1808, ducks of three growths, forty pairs, given by the Duke of Buckingham; the London agent, about seventeen or eighteen, four weeks old; at another corner, a breast of some several kinds, and another of a breed of turkeys, but they were not kept for meat. One counted on the farm, there are no breeders. Butter is made by Wells. Duke of Buckingham has a breed many more ducks than the person now mentioned, and, as far as it was possible to discover, this person sends 400 ducks in a year to London. Allowed, then, forty persons to send only as many, at an average of five shillings per duck, the return of ducks from Aylesbury alone will amount to 4000, per annum. This return has been magnified into 20,000, per annum.

13. Political Economy.

Benefits; extremely bad and dangerous; difficult to be discovered from mere shift; vain, ill-plaid-roads, not to be commented; canals various and useful; grain sent to London at two shillings per quarter. Duke of Buckingham generally established for the poor; no agricultural society in Bucks. Principal manufacturer бумаг and lace.

In calculating the number of acres, Prout the Reporter tried the first system, first shewn by the Bishop of London, of weighing the portion of paper containing the map; he next took an exact copy of Cary's map upon paper, by tracing its outline, after the map was strained upon a canvas blind at a window. This copy was cut out with great exactness by a sharp pointed knife, and then divided into pieces, which were all so laid together, as to form a right-angled parallelogram; another piece of paper was cut into the form of an assumed parallelogram longer than necessary, upon which the pieces of the copy were laid, and bounded by gum-water, so as to fill all parts of a right-angled parallelogram shorter than that assumed; the difference between the assumed parallelogram and that formed by the pieces of the copy of the map, was accurately measured and subtracted from the assumed parallelogram, and equal to the difference of the number of acres in Bucks. Thus then we have the number of acres taken from Cary's map, by weight 296,015, by measure, 301,914. From which, if we take an average, we shall probably state it as accurately as it can be found to be, 295,000 acres; and for the sake of round numbers, we will call 295,500 statute acres.

7754. BEDFORDSHIRE. An irregular parallelogram of 299,000 acres, not much varied in surface, and for the most part a clayey soil. The agriculture chiefly directed to the raising of wheat, barley, and beans, but of an inferior description in many respects. Little pasture; scarcely any market orchards, but good vegetable gardens established at Sandy, on the east of the county, from time immemorial. Great extent of grass; in the lower part, the Duke of Buckingham employed many valuable men in conducting improvements, as Farcy, Smith, Salmon, and Pontey. A valuable set of experiments on grasses, conducted by Sinclair under the direction of the present Duke.

1. Geographical State and Circumstances.

Climate, mild, pleasant, and favourable to the growth of vegetables; rather later than Hertfordshire; prevalent winds, S.W.; coldest wintry N.E.

Soils, chiefly clay, next sand, and lastly in the southern extreme clayey and chalky. Some of the sands very gritty, and producing nothing but bush, others more loamy, as about Sandy, which is supposed to contain the best garden-ground in the county.

Minerals, some ironstone; limestone abounding with ornamental Parsons, and other stones, petrified wood, crypholiths blemishes; freestone, chiefly lime, at Tattatersall.

Laid a large kitchen (a), bake and brewhouse, and washhouse (b), a hall or master's room, with a cellar under (c), a good parlour (d), a dairy (e), besides a poultry (f), closets, and a bedroom and ale cellar under. On the first floor were five, and on the second (fig. 987), four good bed-rooms. The expense of this house on the octagonal plan was 67l; it had been built in the
I. AGRICULTURE OF BEDFORDSHIRE.

123

Agriculture

Square form it would have cost 733%. It is built of brick, slates, and was designed by Mr. H. Salmon, a well-known mechanist, resident at Wolston. The same accommodation a square plan form, a house more convenient for placing furniture (fig. 98b.) Wattle and daub, that is, clay plastered on bridge-work of splinters, or on wood framework, and also the First manner of clay-working, in use in some places, both for farm-houses and cottages. Wise walls found warmer and cheaper than any other, and when whitewashed said to make good cottage walls.

4. Occupation.

Many farms of from 200 to 500 acres; average 150 acres; Duke of Bedford's farms generally of the average size. Farmers much improved by the example of Wolston and the annual meetings. The experiments made by Prince Duke of Bedford were to ascertain the quantities of hay consumed by working oxen; comparison between large and small cattle; the comparative taste for different foods, &c. Trials mostly in hay hands; farms held generally from year to year; some on leases of fourteen or twenty-one years.

5. Implements.

Plough of the swing kind, with a wooden handle and three iron nails on as a mouldboard, one fixed handle, and a loose one called a plough staff; the whole singularly rude, though in general use throughout the country. Improved forms of all machines introduced by the Duke of Bedford's Northumberland manager, Mr. Wilson, and other enlightened men. A good straw cutter, windrow machine, a hay tedder, and also a small horse ploughing machine, invented by the late Mr. Salmon, an engineer of genius, resident on the Duke's estate, and employed by him as an agent.

Formerly three fourths of the county unenclosed, now chiefly enclosed.

7. Arable Land wretchedly ploughed.

Failures, which occur on the clays generally once in three years, badly worked. Uveal crops are failures, wheat, beans, onions, turnips, common on the clays and chalks, soon broken, and hand-hoed. Chicory was tried by the Duke of Bedford, who found it yield ample produce; had twelve acres, which, in 172?, kept six sheep per acre from the second week in April till Michaelmas; four and a half kept ten sheep an acre from the second week in April till 2d July, and then seven per acre to end of October. Sheep thrive well and fatten from denseness.

8. Grass Land.

Of very limited extent, and in many places covered with sedgy ground.

9. Gardens and Orchards.

Gardens of Sandy and Girfard long celebrated for the excellence and abundance of their culinary vegetables. Neil a deep sand, of a yellowish brown colour; products peak, beans, cucumbers, potatoes, parsnips, and carrots, radishes, cabbage-plants, and turnips, sent to market in all directions to the distance of sixty miles. Cucumber chiefly to London, and sold at ten and twenty shillings a barrel for picking. Orche-

About 7000 acres, situated on the slopes of hills on cold marshy plains. Various new plantations formed by the principal proprietors, especially the Duke of Bedford. Figs grown on some of the sandy hills, for burning lime. Some lime trees of the silver fir, and others of the genus Picea at Wolston, platted under the direction of the celebrated Miller; a fine teas, &c. by Pinhey in his Forest Prints.

Four thousand acres of chimly down at Dunstable, not much any where else.

12. Improvements.

A good deal done, especially bees. Elkington's mode said to have been tried with very partial success. Bush and strew-draining attempted on the claysoil, and the moor ploughed a good deal used in the fowries. Irrigation introduced by the Duke of Bedford, and various examples are to be found in different parishes on his Grace's estates. Peat is used as fuel, and also burned for the ashes as a manure; a simple experiment made on manures, by Dr. Cartwright, at Wolston; but no agricultural experiments on a small scale can be depended on.

The dairy at Wolston (fig. 98c.) is a fanciful structure in the Chinese style; but the plan and arrangement is not well calculated for keeping milk and butter cool and sweet.

13. Live Stock.

Cattle a mixed breed of long and short horned Alderley, &c., of which the former bears but six hundred and seventy; dining common on the sands and chalks, sow broad-cast, and hand-hoed. Chicory was tried by the Duke of Bedford, who found it yield ample produce; had twelve acres, which, in 172?, kept six sheep per acre from the second week in April till Michaelmas; four and a half kept ten sheep an acre from the second week in April till 2d July, and then seven per acre to end of October. Sheep thrive well and fatten from denseness.

14. Rural Economy.

Husbandry business generally performed by day labourers; though on most large farms a horsekeeper, cows' keeper, sheep-herd, and kitchen maid hired by the year.

15. Political Economy.

Almost all the cross roads, and many of the main roads, very bad. Grand Junction Canal passes through a part of the county, and is very useful; fairs and markets various; manufactures chiefly linen, a good deal and low; children of ten or twelve years of age acquire the art of plaiting, while their mothers sort and bleach the straw. Lace-making a more sedentary employment, and the women and children generally appear sickly. There are school-mistresses for teaching both straw plaiting and lace-making. Begin to learn to make lace at six or seven years of age; do little good for two years, at ten years earn two shillings a week, at sixteen as much as can be made by the business, or nearly six shillings a week; work in summer from six o'clock in the morning till sunset, and in winter from nine till eleven at night; maid servants scarce in consequence, but poor rates kept down. Some rush mats made near the Grace to the west of Bedford.
The soil is almost uniformly good, but
remariable for no excellence in agriculture. Rapposed are the adjacent practical
State of Agriculture.

1. Geographical State and Circumstances
Climate, tolerably healthy, considering that the east part is
that part is almost bare and not one acre of water from
springs.

2. Soil.
 löed lands in the hands of a few proprietor; the
few freeholders, the remainder almost all copyhold.

Farm-houses, very inconvenient situated, partly owing to
the natural state of the country, and dry sites for farms; some
good cottages lately erected as the only means of retaining farm
servants of any length of time with the same master.

4. Occupations.
Many large farms, though small ones predominated; leases
frequent; to be held in

5. Improvements.
Ploughs, with one handle, originally from Holland; one wheel,
with a plain shaft, is that which is kept sharp, acts as a coulter.

6. Tilling.
Ploughed, with a pair of horses, or three abreast; two crops
and a follow the common rotation; chief crops, wheat, oats,
barley, and potatoes; lands of as much as 300 acres, or more, and
buried or scarified; also on upland; manured and treated as turnips;
seed thresher in the field; straw gathered, and kept for hay or
matted, and also for branding. The land will

7. Grass.
Some good meadows on the one and the pastures
remote from the farm buildings, but are in general rich,
though neglected; require to be pared and burned, and
branched. A good stock of

8. Woods and Plantations.
A good many pollard willows in the fen, and some
plantations.

Great want of a general county drainage; such as that of the
Beds, is impossible if such improvements are not made; and

The chief trade is at Little Baldry, in Leicestershire.

11. Emission.
Bed roads; a lace manufactur at Kibworth; a paper mill
at St. Neots; two lacemakers at Summerfield; and an

Plains, the improvement in general as in Huntingdonshire;
hemp is cultivated more extensively; flax is grown, and
mustard, near Wisbeach and Outwell; a few leth, in
Huntingdonshire; hemp is very extensively cultivated. The
reporter says, a second crop of mustard is obtained by what
they call an English mustard, which is grown up by land which
it has not been cultivated for upwards of a century. Wood is
impossible if such improvements are not made; a

Extensive; some under such a management, and of little value;
other extensive, and, both as hay and pasture, valued in the
district called the Wash, they will carry from one to two hundred sheep per acre, to live to twenty sheep per acre fed
the greater part of the year.

Gardens and Orchards at Fly, Soham, Wisbeach, &c., which supply Lynn and various places, by water carriage,
with apples, cherries, and pears.

15. Street and Plantations.
Some young plantations. The Rev. G. Jenyns, of Botton,
Plains, our old natural pastures, have been much
improved. They are and work the soil in such a manner,
and finds they thrive faster. (That he is mistaken, see 392.)
Ones are grown in various places for the basket manufactory,
and work the soil in such a manner, as well as any crop.

In 174, 1,565,500 acres.

17. Miscellaneous.
The former state of the fen lands, and their degradation to their
present state, is given in length in the report, chiefly from a
commissioner of surveys in the reign of James I., 1604; that

Book

AGRICULTURE OF CAMBRIDGESHIRE.

I.

these fern (a space of upwards of 2S0.000 acres) were once "
of
the nature of land-meadows, fruitful, healthy, and very
g dnful to the inhabitants, and Yielded much re'lief
to the highland counties in time of great droughts.'' Sir W.
Du 'dale
(who was horn 160->, and died 16.SG.I was of the same opinion,
adding as a proof, " that great numbers of timber trees (oaks,
firs, Sec.) formerly grew there, as is plain from
manv being
Sound in digging canals and drains, some of them severed fioin
their roots, the roots standing as thej grew, in firm
earth, below

moor.
On deepening the channel of Wisbeach river, in 1635, the
workmen, at eight feet below the then bottom, discovered a
second bottom, which was s'.onv, with seven boats lying
in it
covered with silt. And at Wln't.lesea, on digging through
the
moor at eight teet deep, a perfect soil was found with swards
of grass King on it, as they were at lirst mown.
Henrv of
ttie

Huntingdon (who lived in the reign of .Stephen, 1 135,1 'de.
scribed this f nny country "as pleasant and agreeable
to the
eye; watered by many rivers which run through it, diversified
by many large and small lakes, and adorned by many
and islands." And William of Malmsbury (who lived woods
in the
first year of Henry II., 1154) has painud
the state of the
land round f homey in the most glowing colours he says
"it
is a very paradise, in pleasure and delight
it resembles heaven
itselt; the very marshes abounding in trees,
whose lengih
without knots do emulate the stars." " The plain
there iVas
level as the sea, which, wiih the flourishing
of the grass
allureth the eye in some parts there are apple-trees, in
others
Tines.'
It appears then, on the authority or the
authors
quoted, that the fens were formerly wood arid pasture.
The
engineers were of opinion that the country in question,
formerly meadow and wood, now fen, became so from partial
embankments preventing the waters from the upland-, going
to the sea by their natural outfalls; want of proper and
sufficient drains to convey those wateis into the Ouse;
negleet of
such drains as were made for that purpose ; and that
these
evils increased from the not embanking the river Ouse,
and the
erection of sluices across it preventing the flux and reflux
of
the sea ; the not widening and deepening, where wanted,
the river Ouse ; and from not removing the gravels, weeds,
eke.

hers with various success followed. The famous John
of
(jaunt (or Ghent, who died in 1393), and .Margaret,
Countess
of Richmond, were amongst the draining
adventurers; but
Gough, in his addition to Camden, says " the reign of Elizah

beth may lie properly fixed on as the period when
the level
began to become immedia elvapubliccase.
plans were
proposed and abandoned between that time and 1634, when
King Charles I. granted a charter of incorporation to Francis
Ear! of Bedford, and thirteen gentlemen adventurers with
him, who jointly undertook to drain the level, on condition
s h°vdd have granted to them, as
a recompense,
y5,000 acres (about one third of the level).
In lMy, this
charter was confirmed to William Earl of Bedford, and
his
associates, by the Convention Parliament; and in
1653, the
level being declared completely drained, the 95,000 acres
were
conveyed to the adventurers, who had expended 400,0(111/.
which is almost 4/. 4s. per aire on the 95,000 acres, and about
If. Ss. on the whole breadth, if the whole
level contain 285,000
acres, and it is generally supposed to contain
300,000 acres.
In ICG 1, the corporation called " Conservators of the great
level of the fens" was established.
This body was empowered
to levy taxes on the 95,00" acres, to defray whatever
expenses
might arise in their preservation but onlv 83,000 acres were
Tested in the corporation, in trust for the Earl of Bedford
and
his associates ; the remaining 12,000 were allotted,
10,000 to
the King, and 2000 to the Earl of l'ortland. At first the levy
was an equal acre tax hut upon its being deemed unjust, a
gradual one was adopted, which is now acted upon. In
the
year 1G97, the Bedford level was divided into three
districts,
north, middle, and south having one surveyor for each
of the
former, and two for ihe latter. Jn 1753, the north level
was
separated by act of parliament from the rest. In addition
to
the public acts obtained for draining the tens, several
private
ones have been granted, for draining separate districts
with
their hunts, notwithstanding which, and the vast
sums expen
much r en,ai "> <° b " done a great part of the fens is
n
now rl:
l!>0b| in danger of inundation
this calamity has visited
them many times, producing effects distressing and extensive
beyond conception, indeed many hundred acres of valuable
land now drowned, the misfortune aggravated by the proprietors being obliged to continue to pay a heavy
tax, notwithstanding the loss of their land."
The interior drainage of the fens is performed in most
places
by windmills, which are very uncertain in their effects.
Steam
has been tried, and there can be no doubt would be incomparably preferable, as working in all weathers.
Embanking may he considered a necessary accompaniment
of draining on the fen-lands. The fens are divided into three
large levels, and each of these levels are subdivided into nu.
merous districts by banks; but as these banks are made of
ten-moor, and other light materials, whenever the rivers
are
swelled with waters, or any one district is deluged, either
bv
rain, a breach of banks, or any other cause, the waters
speedily
pass through these bright, moorv, porous banks, and drown
ail
the circumjacent districts.
The fens have sometimes sustained 20,000/. or 30,000/. damage bv a breach of banks
but
these accidents seldom happen in the same district twice
in
twenty years the water, however, soaks through all fen hanks
every year in every district and when the water mills
have
lilted the waters up out of the fens into the rivers
in a windv
day, a great part of the water soaks back through the
porous
banks in the night upon the same land again. This water that
soaks through the bank, drowns the wheat in the winter,
washes

boots always treads the clay as the
gutter is filled up. Tliis
plan was tried last.summer (1704), on a
convenient firm, and
a hundred acres of wheal were sown on the
land. The wheat
and grass lands on this farm are now all drv,
whilst
around are covered with water. This practice answersthe fens
so well
on this farm, that all the farmers in the parish are
improving
their banks in the same manner, and some
have begun
in adh
jacent parishes."

With respect to embanking from the sea, Vancouver is
of
opinion, that the ground ought to be covered by
nature with
samphire or oiher plants, or with grass, before an attempt
is
made to embank it ; there is particular danger in being too
greedy. " It the sea has not raised the salt marsh
to its irtiittul level, all expectation of benefit is vain, the
soil being immature, and not ripened for enclosure ; and if, again with
a
view of grasping a great extent of salt marsh, the banks
or sea
wall be pushed furiher outwards than where there
is a firm
and secure foundation tor it to stand upon, the bank will
blow
up, and in both casts great losses and disappointment
will
ensue.
Paring and burning is every where approved of, and

1". 7r,
or
40,000/. in his hands, had the art to turn l'rotestant
on tl e
accession of (,)ueen Elizabeth, and appropriated the money
to
his own use; he bought with it an estate at
Barbraham, and
other lands near Bournbridge ; and procuring a grant
from the
crown of the river which passes through them, was enabled
legally to bund a sluice across it, ai d throw as
much of the
water as was necessary into a new cai al of irrigation, ye hich
he
dug to receive it in the method so well knoun, and commonly
practised in Italy long before that period.
1 he canals and
the s.uices are all well designed, anil are the work of
a man
evidently well acquainted with the practice; but in taking
the
waters from them, tor spreading it by small channels
over the
meadows, there does not seem to be the least intelligence, or
knowledge ot the husbandry of watering. No other art is
exerted but that merely of opening in the lank of the
river
small cuts tor letting the » ater flow on to the meadows always
laterally, and never longitudinally, so necessary
in works of this
kind. 'Ihewater thin finds its own distribution, and so
irregularly, that many paits ret eive too much, and others
none at
all.
rrom the traces left of small el annels in different pans
of the meadows, it would appear that the ancient
distribution
Irrigation

'

formed under

l'allavicino is lost, and that we see nothing at
present but the miserable patch-work of workmen ignorant
of
the business. Irrigation has not spread from this example
but might be extensively practised on the banks of all
the

rivers."

aqu.itica.

The com system consists chiefly in suckling of calves and
ot butter
there is not much cheese made, except the
Suham and Cottenhain. The suckling season is
from Michaelmas to Lady-day. It requires, on an average,
two cows to fatten a calf. The cows, when at a distance from
home, are milked in the pasture, and the milk brought home
by a horse or ass, in tubs, slung across
women could not do
this work, the travelling being, after the least rain, very badeven when there is no water to go through. The butter is sold
rolled up in pieces of a yard long, and about two inches in
circumference ; this is done for the conveniency of colleges,
where it is cut into pieces, called " parts," and so sent to
table; its quality is nowhere excelled.
Bullocks of various kinds fattened on grass, and when not
ready in autumn, put up and finished on corn or oil-cake.
Col. Adeane buys in London at a falling market, and keeps till
a rising one before he st lis.
Shicji chiefly as in Huntingdonshire; some Is'orfolks and
South Downs folding on the uplands.
Horses of the cart kind much bred, and considered an article
in which the county excels; they are -very large and bonv
;
black ; with long hair from the knee to the fetlock trailing on
the ground.
A cart stallion has cost 255 guineas, and his colts
have sold for sixty guineas. Horses kipt in the stable throughout the year, at a great expense, because on drv food herbage

AGRICULTURE

1. Geographic State and Circumstances.

Some part of England is more cold and bleak than others. On the Chilham hills, cold, @ winter, January is bleak, severe. The county is

2. Soil.

Soil in three great divisions: red, brown, loam. The Chilham hills, cold, and bleak. There is a considerable portion of loamy soil. Few large estates; church tenures very common; one estate of 30,000, a year, one of 12,500, one of 7,000, one of 5,000, and one of 1,000.

Buildings of the cottage and poor. The cottage is the principal building in the county. It is of the cottage and poor. The cottage is the principal building in the county. It is of

4. Occupation.

Farms generally smaller than in most other counties; few above 500 acres. Leases of fourteen and twenty-one years not uncommon; many of seven years. Farmers in general very ignorant, and many of them very ignorant. Few large farms, the majority of which are held by small farmers. Few large farms, the majority of which are held by small farmers.

5. Implements.

The prevailing mode of cultivating the land is by the plough and harrow. The plough is of the ordinary kind, with a shallow plough and a long, sharp blade. The harrow is a simple, strong, and efficient implement. The plow is the principal implement used in the county. The plow is the principal implement used in the county.

6. Poultry.

Poultry is generally kept, and many of the farmers have flocks of poultry. The most common birds are the cock, hen, and chicken. The most common birds are the cock, hen, and chicken.

7. Fruit.

Fruit is generally grown, and many of the farmers have orchards. The most common fruits are the apple, pear, and plum. The most common fruits are the apple, pear, and plum.

8. Game.

Game is generally kept, and many of the farmers have game preserves. The most common game birds are the partridge, pheasant, and teal. The most common game birds are the partridge, pheasant, and teal.

9. Fish.

Fish is generally caught, and many of the farmers have ponds for the purpose. The most common fish are the carp, tench, and eel. The most common fish are the carp, tench, and eel.

10. Manufactures.

Manufactures are generally carried on, and many of the farmers have factories for the purpose. The most common manufactures are the manufacture of linseed oil, the manufacture of soap, and the manufacture of nails. The most common manufactures are the manufacture of linseed oil, the manufacture of soap, and the manufacture of nails.

11. Agriculture.

Agriculture is generally carried on, and many of the farmers have farms for the purpose. The most common farming is the farming of land for the purpose. The most common farming is the farming of land for the purpose.

Industry is generally carried on, and many of the farmers have mills for the purpose. The most common industries are the industry of flour, the industry of wool, and the industry of leather. The most common industries are the industry of flour, the industry of wool, and the industry of leather.

In 1809 an attempt was made to improve
few, bj letting ,t to Scotch farmers. As
Una originated In consequence of a pamphlet which the compiler.., the |.r, lent work published in 1808, it might be deemed
a detect ill this sketeh if the circumstance were pissed over
without particular notice. It will, no d. ail. t, lout; hi- recollected
in th<- count v ;is at least a ruinous project of wild nil ven Hirers
this being the very mildest term applied to failures in similar
cam's. At this distance of time, looking hack on the matter, as
far as the result affected ourselves, with our natural sangfroid,
we shall state our opinion as to tin- ..u. .<-. of failure. 'Plus resulted principally from too great an\iety, both in the landlord
and tenants, to reap a large benefit; and secondlv, from the
general fall of prices, both of land and produce, which suceaadad to the published report of the Bullion Committee in
1807. Anxiety to Increase the rent-roll induced the landlord
to let the v hole of his estate of nearly Hull) acres, then under
nearly a score ef tenants, to two cultivators, instead of trying
liist tin' ctket of one or two moderate-sized farms under
the

.

In that report a disingenuous attempt is made to attribute
to
the Board ihe merit of the introduction of Scotch farming
into
this and other counties
whereas it was and is perfectly well
known, that the 1' annex's Magazine, the Scotch farmer Gourlay, late Of Wiltshire, and our pamphlet, were
the true causes.
By the tune a second edition ot the Husbandry of Scotland was
called for, Scotch firming had liecome unpopular, and the
Heport mentioned, anil all the compliments to the Board of Agriculture for having introduced it, were withdrawn. A general
account of all the operations on Tew estate by Scotch farmers
will be tound in Designs far Farms and Farm
Buildings in the
Scotch Stale, adapted tu England, CfC. 4to. 1812.

Ll

e involved in (lilficulties, owing to the expenses of new
buildings, roads, drainages, the purchasing up of certain outgoing tenants, and other causes: he found, that though one
person had been willing to buy the estate held on twenty-one
years' leases, yet that it would sell much better if held by
t.n. tots at will
and was thence induced to buy up from the
Scotch tenants the leases granted them two years before, and
v. ,, still unsuccessful
in endeavouring to sell the estate. At
si
the proprietor found himself with the greater part of his
lands in hand and one farm, it is proper to observe, was put
under the management of an Irishman, who rendered himself
not. .nous by some parts of his conduct, and finally
left the
country clandestinely and whose actions have unfortunately
en confounded with those of the Scotch far ners, after
a
the latter had completely left that part of the country.
\\ hen peace was concluded in 1S1 1, land fell still lower;
and
finally this estate w.es sold for less than half what it had
hem
sold tor 111 [809: but still (which may be considered as
remarkable! for about double what was asked for it in 1S07. It
1823 probably not worth a third part of what was
'i
it by the purchaser, from the
change in the times; so
Si
lat even had the original scheme and sale worked

should increase with the rapiditv and universality which they
appear to do. Every acre of pond, properly stuked and well
situated, must produce an annual increase of from eighty to
one hundred pounds weight. If artificially fed, the increase
would be greater or less, if the pond is not so situated as to
receive manure from the circumjacent lands. Bv retail, the
fish here are generally sold at a shilling per pound'; but under
particular circumstances they may sometimes be had as low at
tenpence.

tithes were deposited, is set standing, and measures 101 yards in length and eighteen in breadth. The side walls are only eight feet high, but the roof rises to a great height, and is supported by seventeen stone pillars, each four yards in circumference. The roof is of oak, of which the principal part is thatched with grass. The nave is divided into three aisles by sixteen piers, and the chancel, at the east end, is separated from the nave by two storeys.

One third of the county occupied by proprietors. Farms of all sizes under 1000 or 1200 acres, but few exceeding 300 acres, or under 500, a year. Character of the Berkshire farmer stands high. "A hospitable style of living, liberality of sentiment, and independence of principle, are characteristic of the Berkshire farmer; to which he unites persevering industry and integrity in business, which render him worthy of the countrysides he enjorns." (Dr. Mayor.)

5. Implements.

The Berkshire wagon, one of the lightest and best implements of the wagon kind. The sort of draught chain described and recommended by (Cow 1723), is in use on one estate; the object is to prevent the draught of the trace horse from pulling down the thills. The county plough, a clumsy implement used with wheels; a pressing plough (1711) recently invented; it has three wheels, with the area wedge-shaped, and is intended "to press in the grubs or channels made by the common plough, that no hollow places may remain for the seed to be buried too deep." (Cow 1723). This sort of improvement unusual among amateur agriculturists, who have one implement invented to correct the faults of another, both of course bad. A number of other inventions, including a curious hand threshing machine, ingenious enough, but quite unnecessary, are ignored and deserted at Reading: those on the Kennet, one of the most complete threshing machines in the emporia, what good has been arch they are for the most part agree once the plan of his present farmer manager, Mr. Buns. Having received a plan of it too late for introduction here, we are giving it in an appendix, for the benefit of agriculturists in countries where manual labour is dear, and where running water abounds.

6. Arable land.

The county has from four or five horses at a small price. George III. had two farms, one of 800 acres, cultivated in the Norfolk manner, and another of 450 acres, cultivated in the Flemish manner; 420 of the former, and 450 of the latter, were arable. The whole deeded to the care of N. Kent at Cran's Court, land, and no. The above is describes in the Royal farms near Windsor, and on the Downs. Some hops, woad, flax, and other plants not usually cultivated; seventy acres of lavender at Park, Place, on the side of a chalky hill, originally planted by General Conway, who distilled it at his chief house at the house of a very distinguished manufacturer. As the plants die they are replaced by others from a small nursery plantation. It begins to flower about the end of July, when nearly one hundred women and children are employed in cutting off the flower spikes, which they tie up in bunches, and send to the all-houses in baskets, carried by two men in a cart. The flowers are dried, and sent to the head house after being once mown. The haydairy farmers occupy the poorer upland grassy districts, and the breeders of the sheep the Downs.

7. Gardens and Orchards.

About forty acres of market garden and orchard at Reading, where onions, melons, cucumbers, apples, pears, and peaches are grown. Apples suitable for the London and Bath markets, and culture suitable for the present market season; good apples there and at other places; some elder, anda, and a good many cherries are grown here. The Abingdon orchard of twenty-one acres, containing 541 trees.

8. Horses and Ploughs.

Extent of Windsor Forest, belonging to the crown, 514 acres, including wood and water; private property, called Forest Land, of which acres, are surrounded by a series of high boundaries. The forest is governed by the following rules:凡是 under the government and superintendence of a lord warden, who is elected by the burgesses and the justices of the peace. The steward is the chief head keeper of the several woods, and the under-keeper. Great part of the timber on the forest sold, as is the retained, is truly venerable and picturesque in appearance, but rotten or mildewed in such a way as to be useful for fuel. This rot, or mildew as it is called, seems to be the natural process of decay, and is particularly fatal to beech trees, which are the most found there. The oak, elm, and beech are the most parts of the Thames meadows. Extensive plantations have lately been made on the Duke of Gloucester's demesnes at Baghot, under the direction of his very intelligent managers, Edward Barnes, and Toward. (See Gard. Mag. vol. vii.)

10. Improvement.

An account of the culture of George III.'s farms, by Kent, dated 1790, is given in the volume on agricultural institutions. Oxen are used both in farm and road-work, and the ploughs are the Norfolk wheeled plough and the Suffolk iron plough. At a later period the ironlocomotive plough and, with which two oxen, yoked in collars, will plough, on the light soil of the forest, an acre a day. Hauling the couch manure a good deal practised; the drains filled with straw, rubbish from brick kilns, wood, chimney sweepings, etc.

Pest ash is a manure almost peculiar to Berkshire, though they might be obtained by the same process wherever pest of similar quality can be obtained. Peat ash is obtained from Holton and the ashes extensively used there, and sometimes shipped to this country. In the year 1745, pest was first burnt in Newbury, and in 1755 by a Thomas Riddel, who at the same time spread the ashes on clovers, for which purpose they have been extensively used in Berkshire, "of a height of pest land at that period sold for 5s. per ton; it has since sold, according to the market, from 6s. to 6s. 8d., and is now bought at about 9s. 6d. per ton. Over the stratum of pest, which is about six or seven feet deep, is a good meadow soil, and under the pest is granite. Pest ash is highly esteemed, as the soil is reckoned the best, and is used for firing the ashes of which are most extemely value and have the reddish colour. Pest ash burnt for sale, is mixed with turf and other substances, which gives it a pink tint, and is also mixed with handled spade, from the middle of May to the end of June, and is conveyed from the spot in little wheelbarrows, to a short distance, where it is spread round, and, by being worked over a week, the pieces are turned. This being three or four times repeated, a heap of 5 or 6 yards in height of pest ash is spread, and in the centre of this heap some very dry pest is put, which, not being lit, fires the pest ash down to the rest of the heap. When it is completely lighted, an additional quantity of pest is put upon the heap, and this operation is continued until the whole is consumed, which usually takes a month or six weeks, as quick burning is not approved of. Bain saddle is a kind of pest ash, to which 2 or 3 bushels of foreign ash is added. The heap is commonly of a circular form, and rather flat at top. At first a circular mound of 5 or 6 yards in height of pest ash, or two or three yards deep, and six or seven yards in diameter. The ashes being ridged, are conveyed away in a distance some little distance of twenty or thirty shovels, and put into a house under a shed, to keep them from the wet, till they are wanted to be put on the field. The usual time of applying pest ash is March and April. They are generally run over the land two or three times before the grass is green, and a fourth or fifth time just after the sowing is sown on the land. The quantity is usually from twelve to fifteen bushels, according to the soil and crop. It is supposed that too large a quantity would be injurious. For large, wheat, and peats, they are not applied to at all for winter, nor for early artificial grass, more especially, they are preferred to all other manures. In turnips they tend to prevent the ravages of the fly; and in grass seed the farmers reckon on an acre, manured with ashes, growing manure as flourishing as hay beyond what it would have Gilled without them. The effect is supposed to be of no longer duration than two years. On meadow land, from fifteen to twenty bushels are advantageously to be put; they much improve the grass.

11. Live Stock.

No particular breed of cattle; long horned most common. A diehard tract in the west of the flat of White Horse; much cutter made; but much much made. In the south of Berkshire, it is called a good deal stuck in some places. Buttock, and in the south, and in the north, to the excellent flavour, and sell better than other cheeses. The curds are well thrown up in the hands, then pressed in a wooden mould in the shape of a flower pot, and afterwards suspended from beams, ropes, or pegs, in an airy and well-ventilated place, like a pine apple. Salt is then rubbed over them, or they are steeped in brine; weight, 50lbs. per head. The same breed of cattle is raised in the north; there being a large number of fairs where farmers are in a large number of fairs. (See 9th, 9th, 9th, 9th."

Sheep, a native breed known as the Berkshire polled, or mottled (for 992.); strongly marked, but much more than this, and than for the purposes of agriculture, and that one third of the number might be saved. The breed is the Northamptonshire breeders; many, after being kept a year or two at work, are sold for draught.
7791. GLOUCESTERSHIRE. A surface of nearly 800,000 acres, in three natural divisions; the Cotswolds, the vale of the Severn, and the Forest Lands. Great part of the county is under meadows, pastures, and orchards; and cheese and cider are its known agricultural productions. It is also a manufacturing county, and its fine broad-cloths are extensively manufactured. There is no very eminent gentleman agriculturist. Tennant farmed a small estate on the Chilterns.

1. Geographical State and Circumstances. Character, cold and bleak on the Cotswold hills; mild in the vale, which lies open to the south winds; on the sand, soils of the forest district, the harvest is sometimes cut a fortnight earlier than in the valleys. Soil of the Cotswold is all calcareous loam or stonebrash; in the forest district, stonebrash, loam, or fertile loam, and are found in places a strong clay and peat earth; the forest district is generally sandy loam, sand, or peaty earth. In the valleys, in the Cotswolds, but iron and coal in the Forest of Dean, both worked, Lead found in the limestone rocks, and sometimes a part of the vale; not worked. Though iron ore be abundant in the Forest of Dean, only a small quantity is raised. Of coal, the county is not so fortunate as the former, for the river Thames and the Severn require much for the purposes of navigation. Of timber, none are of much value, except in the counties of the Severn, where are salmon, lampreys, lamprams, char, sole, eels, sardines, eel, plaice, conger-eel, purpose, and sturgeon. In the forest district, the supply is much more numerous, always thickly covered with the broad leaf clover, which is manufactured in a great variety of goods, and is much used for hay, and for haymaking, and for foraging, and for feeding both cattle and horses. The most of the clover is raised in the vale of the Severn, where the climate is mild, and the soil is fruitful. The clover is not grown in any great quantity on the Cotswolds, nor is much of it raised in the forest district.

2. Property. Largest estate 8000 acres, a year among the nobility, and 3000 acres among the gentry in the county. Houses, chiefly freehold, some copped, and about one-fifth rented. Estates under the lease of Gloucester, left out on lives; those of the corporation are for the same time, that is to say, for the renewal of a life, and one-half of the improved annual value.

3. Buildings. Many handsome seats; farm houses and cottages on the Cotswolds built of freestone, and covered with some tiles; on the forest lands, chiefly thatch, and about one-fourth rented corporation houses. Estates under the lease of Gloucester, left out on lives; those of the corporation are for the same time, that is to say, for the renewal of a life, and one-half of the improved annual value.

4. Occupation. Farms differ much in size; few exceed 1000 acres, or fall short of 300 acres. Some grain farms in the vale of 500 acres, but 200 and 300 more common. Lease of three years most common, next of seven years, not many of fourteen, and those of longer tenure are for rents of considerable value.

5. Implements. A narrow-wheeled wagon in general use among farmers. Various ploughs; a short-beamed one with a large draw bar in use on the Cotswolds; in the vale a clumsy swing plough. Lombard's drawing-plough much in use with the improved draught apparatus, and in the west. Vaccination and inoculation are general, and all other medicines are in use, excepting some, which are in immediate use. Vaccination and inoculation are the most popular. The common use of medicines is for the treatment of smallpox, scarlet fever, measles, and diphtheria.

6. Enclosing. The first enclosure during Queen Anne's reign; eleven during the reign of Geo. I.; and a period of seventy years during the reign of George III. Hedging of white thorn, on which the reporter observes medlaries might be grazed, and raised in great plenty; but the thorn must be cut down. The hay will not be cut as long as the clover is growing.

7. Arable Lands. 6000 acres; much rough ploughing on the Cotswolds lightens the staple of the small fields; seven horses often used in the vale terms. In the common manner. The warren, which rise through beds of blue clay, are often strongly waterlogged in the winter.

8. Grass. Very rich meadows on the Severn, overflowed during winter and spring, so that the farmers depend on a crop. When the salt water overflows the meadows, the grass is turned, and grazed by hogs and cattle that require feed and spring food. In general meadows are mown and pastured alternately, excepting near Gloucester, where abundance of mowing is obtained. Herbage, plants, and grass grown on the Cotswolds, but little in the vale; still more much cultivated on the stone-brash soils. Grass lands fed in general from May to the end of September, and then the cattle, unfinished, are taken in and completed with hay, given, and other artificial food, and set at grass. The Orchards are generally much improved, and made to yield good crops.

9. Gardens and Orchards. Most of the cottages, such as they are, have gardens, and almost every farm its orchard; but large ones so as to be in a

Rabbits kept in warrens, in one or two places; and one gentleman has an enclosure of a pure white, the skins of which sell high for trimming.

12. Political Economy. Roads for the most part good, especially since a part has been taken from the canal and turned into small wheels, and are lighted, and alarums, in most places. Canals and navigable rivers everywhere spersed, that no part of the county is further than twelve miles from one or other, or the nearest canal. Much industry in the weaving of linen, and woollen goods, made in the market town of Gloucester, and the other smaller towns of the county, as much in the weaving of cotton, and other cloths, and other materials, as well as the spinning and weaving machines, introduced. A little drayage (fig. 221), in use for extracting, the corn thistle (serrata) arvensis from cornfields, which is much used for feeding cattle.

The Berkeley Agricultural Society, established in 1794.

1. Geographical State and Circumstances. Character, cold and bleak on the Cotswold hills; mild in the vale, which lies open to the south winds; on the sand, soils of the forest district, the harvest is sometimes cut a fortnight earlier than in the valleys. Soil of the Cotswold is all calcareous loam or stonebrash; in the forest district, stonebrash, loam, or fertile loam, and are found in places a strong clay and peat earth; the forest district is generally sandy loam, sand, or peaty earth. In the valleys, in the Cotswolds, but iron and coal in the Forest of Dean, both worked, Lead found in the limestone rocks, and sometimes a part of the vale; not worked. Though iron ore be abundant in the Forest of Dean, only a small quantity is raised. Of coal, the county is not so fortunate as the former, for the river Thames and the Severn require much for the purposes of navigation. Of timber, none are of much value, except in the counties of the Severn, where are salmon, lampreys, lamprams, char, sole, eels, sardines, eel, plaice, conger-eel, purpose, and sturgeon. In the forest district, the supply is much more numerous, always thickly covered with the broad leaf clover, which is manufactured in a great variety of goods, and is much used for hay, and for haymaking, and for foraging, and for feeding both cattle and horses. The most of the clover is raised in the vale of the Severn, where the climate is mild, and the soil is fruitful. The clover is not grown in any great quantity on the Cotswolds, nor is much of it raised in the forest district.

2. Property. Largest estate 8000 acres, a year among the nobility, and 3000 acres among the gentry in the county. Houses, chiefly freehold, some copped, and about one-fifth rented. Estates under the lease of Gloucester, left out on lives; those of the corporation are for the same time, that is to say, for the renewal of a life, and one-half of the improved annual value.

3. Buildings. Many handsome seats; farm houses and cottages on the Cotswolds built of freestone, and covered with some tiles; on the forest lands, chiefly thatch, and about one-fourth rented corporation houses. Estates under the lease of Gloucester, left out on lives; those of the corporation are for the same time, that is to say, for the renewal of a life, and one-half of the improved annual value.

4. Occupation. Farms differ much in size; few exceed 1000 acres, or fall short of 300 acres. Some grain farms in the vale of 500 acres, but 200 and 300 more common. Lease of three years most common, next of seven years, not many of fourteen, and those of longer tenure are for rents of considerable value.

5. Implements. A narrow-wheeled wagon in general use among farmers. Various ploughs; a short-beamed one with a large draw bar in use on the Cotswolds; in the vale a clumsy swing plough. Lombard's drawing-plough much in use with the improved draught apparatus, and in the west. Vaccination and inoculation are general, and all other medicines are in use, excepting some, which are in immediate use. Vaccination and inoculation are the most popular. The common use of medicines is for the treatment of smallpox, scarlet fever, measles, and diphtheria.

6. Enclosing. The first enclosure during Queen Anne's reign; eleven during the reign of Geo. I.; and a period of seventy years during the reign of George III. Hedging of white thorn, on which the reporter observes medlaries might be grazed, and raised in great plenty; but the thorn must be cut down. The hay will not be cut as long as the clover is growing.

7. Arable Lands. 6000 acres; much rough ploughing on the Cotswolds lightens the staple of the small fields; seven horses often used in the vale terms. In the common manner. The warren, which rise through beds of blue clay, are often strongly waterlogged in the winter.

8. Grass. Very rich meadows on the Severn, overflowed during winter and spring, so that the farmers depend on a crop. When the salt water overflows the meadows, the grass is turned, and grazed by hogs and cattle that require feed and spring food. In general meadows are mown and pastured alternately, excepting near Gloucester, where abundance of mowing is obtained. Herbage, plants, and grass grown on the Cotswolds, but little in the vale; still more much cultivated on the stone-brash soils. Grass lands fed in general from May to the end of September, and then the cattle, unfinished, are taken in and completed with hay, given, and other artificial food, and set at grass. The Orchards are generally much improved, and made to yield good crops.

9. Gardens and Orchards. Most of the cottages, such as they are, have gardens, and almost every farm its orchard; but large ones so as to be in a

making cider for sale, are found only on the slopes of the hills and in the vale and forest district. The stocks are planted in the orchard when six or seven feet high, and they assert themselves on pasture, and sixteen or seventeen on arable lands. A year after planting they are grafted. Sometimes fruit trees are planted in the hedge rows; hedges are often composed of apple seedlings, raised from the kernels in the cider mill; and here and there the farmer often leaves a stem in the shee the general height of the hedge, and grafts. It frequently also weeds are allowed here and there to rise into trees, and their fruit is used with that from grafted trees, in crushing for cider. Grapes are inserted in the clover manure, at seven feet from the ground, two in each stock; if both succeed, one is removed the following spring, and the stock sloped to the remaining graft, to prevent the lodging of water, and clected seriously, to facilitate the growth of bark over the wound. After grafting, "buds," that is, invered wicker baskets, riding about two feet high, are fitted to the stock, which serve at once to guard the graft and direct their shoots to a proper form. The stock is next protected from cattle or the plough harnes, by four posts placed round it, with six tiers of small stakes, six tier of rails; by two broad posts and rails; by a bundle of thorn branches; by planting a thorn or briar along with the stock; or by using a sheet of the creeping ramson, which round the stock. The mode of planting a creeping rose with the stock, it is advisable to form it round, so as to find the cheapest and best; but it must evidently improve the soil. Framing is not attended to by young groves or orchards or other trees, as ought to be the trimmings of moss and mistress. Grafting the branches of old trees often practised with great success; a young stock grafted will probably produce a bushel of apples in twenty years, but a branch grafted bears the second year, and the third year, and the fourth year, and which is quite unsuited for field orchards. Grafted trees bear little the first three years, and their produce increases till fifty years, and is then ten or fifteen bushels; an apple will bear 100 or more years from this period, and often much longer. Cider-making. Best orchardists shake off the fruit, and never bear the cider. The time for shaking the old trees is when the fruit is shaken by a person in the tree, and those which adhere afterwards are left to rot and become manure. Some trees are used by large, and the hand-mill by small farmers; the cylindri the hand-mill of wood, and fluted; sometimes there are two pairs of cylinders, one finer fluted under the first pair, and in other cases the cylinders are set wide the first time the apples are passed through, and closer the second; the other processes as usual. Some of the various species of Maples are the style of the forest district makes the strongest and richest cider; it is often valued equal with foreign wines, and sold at extravagant prices. Ciders from the Haglo crab, golden pip in, and Longeville woods, are next in esteem. The white- must, woodcock, and hall a dozen others, are fine old fruits, but now going off.

Derry from the squash pear is esteemed the best; and next from the Heulp and sack.

Table-fruits, where farmers live near canals, pay much better than those of the elder kind; especially those of the keeping varieties, such as the golden and Muscadine pippins, Longuey ruses, &c.

Most extensive on the Cotswolds; the sorts there bee and saffy timber sold to dealers, who convert it into the spot for scattering for gun-stocks, middle-trees, hodsteads, chairs, and other cabinet woods. The price for the rough wood is some fine old specimens of chestnut, elm, oak, and ash in the vale. Forteeth chestnut, 300 years old, in the time of King John, in the Forest of Dean, of a considerable quantity of good timber belonging to government, and nearly 3000 acres lately planted with acres. The method of planting is the same as in the forest or ground; then taking off about a foot of turf, to set two or three acres a year. Some stock in a setting pin: afterwards to invert the turf upon them, and, by way of raising a fence against hares and rabbits, to plant two or three strong rows, which are seldom thinned till they have attained the size of top poles, and then are left at twelve feet distance from each other, with an allowance of six inches in the center. By growing thick, no side-shoots are thrown out, which supposes the neces necessity of pruning: the young trees, which are drawn at the first thinning of the sets, and, as they grow, are thought, grown equally well with those that have not been removed, and pro provided timber as thick as the chestnut, or a little thicker, as "that which is raised immediately from the acorn." The "whiten," or sarsaparilla, is a native plant of the woods, and several coppices on the Welsh side of the Severn; and, what is singular, ropes for hatters, plough traves, violin presses, 994, draw wells, and fishery logs, &c. are made from it as

994

in Wales. These ropes are found to contract and expand less from moisture or drought than hempen rope. The bark is stripped off about Midsummer, dried like hay in the sun, and more frequently is found between the leaves of the tree in the parish of Arlingam: the fruit shipped to distant places, and the timber sent to Birmingham for gun-stocks.

Artificial plantations, to a great extent, made round gentle places on the Cotswold hills. The other in beaks on the Severn.

11. Improvements.
Bills of the Severn inundations were frequent; but a commission of severs have received lands and flood-gates, which protect upwards of 1200 acres.

places private banks or floodgates on the rivers or banks of ditches are placed, and operated by the alternate influence of the tides.

Dressing much practised; both in the turf, stone, wood, stack, and field. The turf is cut by the common stacker, or twelve horses, or worked by a long lever and axle (465), by which one horse gains the power of thirty. Before the mow drainage plough is used, it is a good practice to turn off the soil from the common plough; on the side of the road, the soil is spread for the other way. The ground of the improved district, the award being afterwards turned back to its place, completely covers the aperture, and prevents the washing of the roads. The long-continued drought of the summer of 1856 opened many drains which were cut by Lambert's plough, so many, that the bottom was clearly seen; while many that have been done by hand have formed still wider, and have probably not and never will do any good at all. In both instances there is reason to think, that this would not have happened if the open drains were kept in good order, and the turf first turned back, as recommended.

Water of underground streams taken from low meadows in one parish by a wheeled driven by the water of sur face.

Parking and burning practised on the Cotswolds; weeding corn generally.

Chaff is chiefly pursed in the valleys of the Cotswolds, ad joining rivulets, and especially the Coln and Cherwell. Carried to greatest perfection in the parish of Shot. They first went, and are here under the Rev. W. Wright, who wrote several tracts on the subject. When the last great rains in November bring waters down in a muddy state, it is let into the meadows. In December and January the land is kept sheltered by the waters from the severe and frosty nights; but in March, the water is let entirely off, to give air and prevent the roots from rotting. In February great care is required. If the water now appears long on the meadow, a white scum will generate, which is found to be very injurious to the grass. On the other hand, if it be taken off, and the land exposed to a severe frosty night, without being previously dried for a whole day, much of the tender grass will be cut off. Towards the middle of this month less water is used than before, keeping the land rather wet than watered. At the beginning of March there is generally in such meadows plenty of pasturage for all kinds of stock; the water, however, should be taken off nearly a week before cattle are turned up, and a little hay at night during the first week is very proper. It is the custom with farmers to spring耦 the land with clover, or even fold, with a little hay. The meadows, however, must be entirely clear of stock by the time the next month of April is arrived on, that the crop may be much injured, and the grass become soft and woolly, like leathern. After spring-sowing the water is let in again for a few days. It is remarked that autumnal, winter, and spring watering will not occasion roast in sheep; but if the water be used for a few days in any of the summer months, the pasture become unsafe for such stock. This is conformable to the general idea of rod, viz. that it is occasioned by autumnal moisture, and is seldom known to any considerable extent without a long continuance of warm air. A wet summer, therefore, is always productive of the disease in the vale. The general advantages of watering are, that the land and grassage are considerably improved, without manure; and the crop is not only full and certain, but also...
burned cows of Bakewell and Fother. In most parts of Herefordshire other breeds of cattle may be seen in the land; does not always produce the most marketable cheese; often the cheese is made in the valley of Evesham, and is itself of tolerably good quality; large quantities are exported to France, but the quantity on the market is usually small; but on the other, it was difficult to make any tolerably good. The large market town of the Cotswolds, which produced, was the excellent cheese; it was only half a mile from the town, and half a mile from the market place. In the market town of Harfordest, Pennsylvania, two grasses adjacent to each other, it was decided to enrich with bathing with dung, and sheep feeding, the quantity of milk will be increased, but the quality in tolerably large measure. This is the same as in the Cotswolds, which did not grow there before; and at the destruction of some that did. The cheese does not only produce in the Cotswolds, but the market, where it is sold, for the consumption of the town; it has a tendency to raise the price of milk, and lower the price of cheese.

The Production. Best cheese not attempted while the cows are on hay; generally commences about May, when the cows are turned out. It is customary to enrich the cheese in the morning, and at the same hour in the afternoon; the cheese-factory discovers the "loved" cheese by treating them with some

Sheep. Principal breed the Cotswold; now very much mixed by crossing with, and on, and labour is paid for according to their services. Markets are in the Cotswolds, and in the valley of Evesham. Extensive iron works in the forest; the best iron in the kingdom made at Horsham; rails made at Littledean. Articles of agriculture at follow and cheese, bacon, cider, perry, grain, and salmon, to the extent of nearly 100,000 per annum; the same. The most rich and salubrious; the best grass on the market. It is divided into the north, the middle, and the south, or Westmoreland, including all counties.

6. Arable Land.

Hops grown to great perfection, and fruit trees generally abound; and though the rate of formidable is not only mulberry, but figs, quinces, and loquats, and fruit trees, and many others, and among its productions. (Pomeroy's Worcestershire, 1794.) Pitt's Report, 1807. Marshal's Review, 1818.

6. Arable Land.

Fallow ploughed four times, which is rather rare in Eng- land, and the same. It is divided into the north, the middle, and the south, or Westmoreland, including all counties. (Pomeroy's Worcestershire, 1794.) Pitt's Report, 1807. Marshal's Review, 1818.

Agriculture of Monmouthshire.

7. Grass Land. "Some farmers insist on it that rushes shelter and protect grass, and will not allow them to be removed by draining or otherwise."

8. Gardens and Orchards. The latter very general on a small scale; apples for eating much in demand at the iron mills; best orchards and hop-gardens in the lower classes of society. Lettuce culture on apple trees and elder, as applicable to the Isle of Jersey, is applied to the survey.

9. Woods and Plantations. County long famous for the site of its oak; stock now much diminished. The establishment of village and parish libraries recommended; and a paper on the subject copied, which appeared in the Worcester Journal, as well as other evidence, the writer of this paper is Sir Richard Phillips. The plan is excellent, and would probably, in the course of some years, have the effect of raising the lower classes of society. Lettuce culture on apple trees and elder, as applicable to the Isle of Jersey, is applied to the survey.
1. Geographical State and Circumstances.

Climate, remarkably healthy; west winds the coldest; warmest in summers; very little frost or snow.

Soil. A marly clay of great fertility extends over most of the country, and is to be found all around, but more especially on a clayey tract between Hereford and Leominster; the highest lands in the south are more sandy.____________

There are two hills in the West as high as any other hill in England; Wye and Zetland, from the prevailing produce there in former times.

Minerals. Iron is in the immediate neighborhood of some manufactories; yellow ochres, pipe-clay, and fuller's earth, but only the latter worked for their copaltic use. There are two extensive coal-measures in the Wye, but, owing to the wars and illegal practices, not so abundantly as formerly.

2. Grounds

Gur's Hospital, Duke of Norfolke, Earl of Oxford, Earl of Essex, Sir T. Cornwall, &c., the largest proprietors. The estates divided into tracts of from 400 to 600 acres. A number of estates from 400 to 1000, per annum. A constant number resident on their four estates, and cultivated and managed in good style, with a view to the introduction of the best agricultural practices. The tenors of cow-kind and housethrough a few in places, but are generally mulified by will.

Small seats of proprietors, as Hon Lacy, Hampton Court, Downton Castle, &c. Old farms, houses of wood, ill-decorated, and generally in a state of dilapidation. The Hospital at Hereford and other estates. Cottages very humble, and of an inferior construction. Strayable, lately cultivated from some cottages, for the encouragement of success and profit.

4. Occupation.

With a view to the decline; few opportunities now by which an industrious couple can devote 50l. or 100l., acquired by personal industry, and in some cases, the fruits of their family, and pass their latter years in comparative independence. Hence marriage on the decline, and lassitude among the increase. Herefordshire has a large amount of commons and waste lands, to be disposed of for 2 to 500 acres, as ably best for the country. "The old-fashioned farmers, many of whom are now in active employment in agriculture, with great hesitation, if not reluctance. When its unity is confirmed by repeated trials, he will often lose a property in the water, and fail in the experiment and the risk to whom he recommends or suggest it; and happily the animal.of this period, more on the minds of agriculturists, who possess the means and the spirit to undertake the production of those fine limits of twenty-five acres in three periods of seven years, determinable at the end of each period by either landlord or tenant.

Plough, called the light lima, without a wheel, and drawn by one horse, has been for ages in fashion; but often the yoke is the usual mode of harnessing. Various improved implements by the amateurs, but none in general use.

Wheat principal grain cultivated, and generally sown on a fallow ground. Some of the best wheats of Herefordshire; sown in lime and lime, to guard against vermin and hailstones. " The wheats of Hereford and Cheshire will, steep in water and then envelope in lime, and his wheat was as free from smut and other diseases as that of his neighbours from London. He has a good deal of cultivated wheat, and chiefly disposed of to Bristol dealers.

Fertilised meadows on the Wye, Frome, and Lug; mown and red. Not a county for home consumption, saltum, and the future; but in the course of time, and the process of building. T. A. Knight, with that accuracy and skill which he is known to possess on all subjects connected with agriculture and natural history, has proved by experiment, that equal quantities of milk in Herefordshire, and Cheshire will produce unequal quantities of curd, highly to the advantage of Cheshire; and Ettore, that better cheese has been produced in Herefordshire than in Cheshire. When it has been all... and Cheddar will, steep in water and then envelope in lime, and his wheat was as free from smut and other diseases as that of his neighbours from London. He has a good deal of cultivated wheat, and chiefly disposed of to Bristol dealers.

The adoption of Herefordshire appears to be more rich when making of cheese. T. A. Knight, with that accuracy and skill which he is known to possess on all subjects connected with agriculture and natural history, has proved by experiment, that equal quantities of milk in Herefordshire, and Cheshire will produce unequal quantities of curd, highly to the advantage of Cheshire; and Ettore, that better cheese has been produced in Herefordshire than in Cheshire. When it has been all... and Cheddar will, steep in water and then envelope in lime, and his wheat was as free from smut and other diseases as that of his neighbours from London. He has a good deal of cultivated wheat, and chiefly disposed of to Bristol dealers.

5. Agriculture.

Some experiments have been tried in the Wye, and such like, with the best success. There are, however, in the county, many good farms, some of which have been conducted in a manner most worthy of imitation. Herefordshire is a county that produces a variety of important agricultural products, and is distinguished for its sheep. The county is famous for its Hereford cattle, and is noted for its dairy produce. Herefordshire is a county that produces a variety of important agricultural products, and is distinguished for its sheep. The county is famous for its Hereford cattle, and is noted for its dairy produce.

6. Improvement.

Herefordshire, being a large county, breeders direct their attention to producing that form of animal best adapted for their particular purposes. The milk of the Herefordshire breeder has been directed to the improvement of his cows; and for the use of the grazier, the Herefordshire is noted for its dairy produce. Herefordshire is a county that produces a variety of important agricultural products, and is distinguished for its sheep. The county is famous for its Hereford cattle, and is noted for its dairy produce. Herefordshire is a county that produces a variety of important agricultural products, and is distinguished for its sheep. The county is famous for its Hereford cattle, and is noted for its dairy produce.

7. Gardens.

The herbaceous and flowering plants, and the apples and pears, are very highly cultivated, and are found in every part of the country. The soil best adapted for the cultivation of plants and fruits is deep and moist. This is to be found in the Wye, and is cultivated with the greatest care. The soil best adapted for the cultivation of plants and fruits is deep and moist. This is to be found in the Wye, and is cultivated with the greatest care.

In particularly form exceptions, and flourish most in a hot and dry climate. The Herefordshire breed, being the most productive of milk, is also the most productive of milk in Herefordshire, and Cheshire will produce unequal quantities of curd, highly to the advantage of Cheshire; and Ettore, that better cheese has been produced in Herefordshire than in Cheshire. When it has been all... and Cheddar will, steep in water and then envelope in lime, and his wheat was as free from smut and other diseases as that of his neighbours from London. He has a good deal of cultivated wheat, and chiefly disposed of to Bristol dealers.

8. wooded and pastured

Herefordshire is the most wooded and pastured county in England. It is famous for its timber and its dairy produce. Herefordshire is the most wooded and pastured county in England. It is famous for its timber and its dairy produce.
approach two opposite points at the same time, they will never be able to reach either. Where the soil is well calculated for the dairy, every attention should be paid to obtain and improve the best sorts of milking cows and where the ox is kept to a proper age as a beast of draught, nothing conducing to his excellence ought to be neglected. A cow must, however,rive milk enough to keep in calf hit, or it is defeated for breeding a good ox; because the calf would be spoiled before it had acquired the proper age to be used.

Sleep. The provincial levels, the Ryeland, named from the sandy district in the neighbourhood of York. They lamb in February, and March; but during winter, and particularly in time of lambing, the store flocks are generally confined by lights in the barn. In building a barn for that purpose, they are sometimes fed with hay and barley straw, but much more frequently with peat. Some breeders custom them to the cot only in severe weather, and in lambing time. The practice was derived from the Flemings, and introduced into England about the year 1660. A cross has been made between the Ryeland and the new Leicester sorts to the advantage, perhaps, of the breeder who is situated on good land, but certainly to the detriment of the breed. A cross between the Ryeland and real Spanish seems the most probable mode of adding to its form and value. Dr. Parry's experiments have been sired on a half. (1752.)

12. Rural Economy. If a certain proportion between the price of labour and the average price of wheat could be fixed by law, seem to render the applications for parochial aid necessary only in cases of a very large family, or unusual illness, or secret reasons, or any other real emergency the measure, it is presumed, would be honourable to the country, would stimulate industry and thrift, would check dishonesty, and endear to a numerous class their own soil.

13. Political Economy. Roads formerly bad; now improving; materials, coarse limonites. Gloves, to a small extent, manufactured in Hereford. An agricultural society established in 1739, which has given many premiums, and done much good.

785. SHROPSHIRE. A surface of 800,000 acres; in general flat, but with hills of considerable height on some of its margins. The soil is chiefly clay, but in part light turnip land; both are devoted to the raising of sheep. They are also practised to a moderate extent, because the greatest improvement in the county is the Marquis of Stafford, whose extensive and important operations on the estate of Lilleshall are described at length by Loch, in his Improvements of the Marquis of Stafford's Estates, 1819. (Bashkton's Shropshire, 1794. Pymsey's Shropshire, 1863. Marshall's Review, 1819.)

1. Geographical State and Circumstances.

Climate. Considerable difference according to the soil and surface; more warm on the eastern side than in the middle of the county. E. winds prevail in spring, and W. in autumn. Snows are not so general on the coast, and the former rather predominant. S. W. side of the county variable; thin soil upon clay or rock; extensive tracts of hills and waste; and most sorts of soils except chalk and flint.

Minerals. Lead in granulated quarts very productive. Copper-ore is worked. Coal is not worked. Coal measures generally on the eastern side of the county; lime, building-stone, chalybeate and spar in considerable places. At Kirkly Waek a spring of salt water, used for making salt at a work established at Worbridge. Extensive veins of coal on Coalbrook Dale, where the first cast-iron bridge was erected by Mr. Telford about 1750.

Waters. Twenty-two sorts of fish found in the Severn in Shropshire. Salmon in season from Michaelmas to May.

2. Property.

Estates of from 10 to 25,000 acres, and an infinite number of freeholders. Some estates are, of course, more or less cultivated, but the lands upon some customary tenants have been franchised to copyholders upon receiving an equivalent in money.

Some good new mansions; above eighty of these named in old maps become farm-houses. Four towns generally on villages. Excellent new ones on the Marquis of Stafford's estates. (Fig. 500.)

Comfortable cottages with gardens much wanted. Some public observations by Pymsey; prescribes no particular forms, but suggests the impropriety of making them, or indeed any other object, bear an exact appearance, intended to contradict their inward use; all cadastered or gothicised cottages, all church-like barns, all large and grand buildings, are altogether abominable. They are intended to deceive, and they tell you that they are intended to deceive. It is not pleasant to see forming a thing like building, but that impression on the position effected is rarely gained; it amounts only to imposition attended with, or could the deceit succeed, it would only present a prospect with fewer proprieties about it than there really are. Almost every species of country building has a good effect, if properly placed and neatly executed; and what are the best ornamental, or indeed the most disgusting, of their appendages, come to shock when supported by the relative situation they stand in, allowing their necessity and their use. A dell or holl in a farm-yard creates no disagreeable idea; but connected with a Gothic gateway or embattled tower, it is bad. Cattle protected by the side of a barn form a picturesque group; but sheltering under a Grecian portico, the impropriety is glaring. Linen hanging to dry on the hedge of a cottage may be passed without disapprobation; but the clothes of men, women, and children surrounding the eel of an unfeeling large family, of usual illness, and sordidness, are paid to upon the increase of the contrast. On the other hand, a fine-dressed man with miserable cottages may be compared to the laid clothes and dirty linen some foreigners were formerly accused of wearing. The whole of a gentleman's estate should be his honourable and noble; the villager should be one object in the scene; not shut out from it. There may be a little more polish about the mansion, but it should not be an unpleasant contrast to the surrounding objects. The face of no country is bad but as it is disregarded by artificial means; and the churlish and best improvement is merely to remove what offends, and to take care that the building or fence that is wanted are neat and appropriate, exhibiting distinctly their real intention. Pymsey is a friend to single cottages, the road may have more cases of continuance arise between them. On the other hand, in illis poor people have frequently the merit of fortifying their differences; and then the assistance they are inclined to give each other is made more easy by near-
4. Occupation.

On the borders of Wales the farms are small, many not exceeding twenty acres; on the east side of the county from one to forty acres is the general average; work along with their servants; wives brew, bake, dury, and at spare hours spin, and get up a piece of linen cloth for sale every year. Dyes for linens are very common. Bolton of Kivall has taken great pains to prepare printed leases, which answer very well. The term for remnants is seven, fourteen, or twenty-one years. By being printed the farmer can read them at leisure.

5. Implements.

Plough with two wheels, drawn by four or five horses, or six or eight oxen, in the strong lands, and two horses with a boy to drive in the turnip soils. Various improved implements and threshing machines: some excellent mills on Lord Stafford's estates, driven by steam.

Most practical, and still going on. Fencing hedges is usually very ill done in Shropshire; it is a business which requires great nicety and judgment, and that care is necessary to perform the work in general; who in the first place cut down hedges, through mere ill-sense, instead of upwards, and so expose the heart of the plant to the weather. Many miles of hedges lately planted on the Stafford estates.

7. Arable Land.

Following very badly done on the strong lands. Common crops of the county wheat, barley, oats, peas, and turnips. Peas found not to hold well unless grown on a sharp gravel or sand; those grown on clay given to pigs and hares. Some hemp and hops cultivated.

8. Graze.

Some natural meadows on the Severn and other rivers; not much attention paid to them. Artificial herbage and grasses grown on the turnip fields.

9. Gardens and Orchards.

Many farmers have small orchards, from whence they make a little cider for home consumption, and on the commons of Herefordshire and Worcestershire the orchards are larger, and cider is made for sale.

A good deal of hedge-row timber, and some fine oak woods; also numerous young plantations. Narrow-leaved elm is reckoned an excellent hedge-row tree, but the broad-leaved better timber, and less difficult as to soil and situation. In this county few persons will vary their relations in any but the best oak timber, which contributes much to its scarcity.

11. Improvements.

Marl used, and some rotation. A good deal of draining done with hawks; sometimes season wood. Some bog drained in Elkington's manner. On the Lillieshall estate of Lord Stafford (fig. 999.), in 1816 and 1817 there has been executed about 17,000 yards of embankment; 27,000 yards of water course deepened and scoured; 46,000 yards of main ditches made or

999

deepened; 315,000 yards of fence-ditches deepened, rounded, and straightened; 49,000 yards of old fences stockd; 50,000 yards of new quick fences made; 21,000 yards of turf draining, with and under ground draining, laid with tiles; besides the erection of many new farm houses, of the most commodious plans and substantial execution. To have an adequate idea of these improvements effected by this most fortunate and pious nobleman, it is necessary to peruse the very interesting work of Leech already referred to.

On the Wildmore estate of Lord Stafford (fig. 1000.) excellent roads have been formed; so that several parts, before inaccessible in winter and during wet weather, may now be approached at all times with ease. The effect, as Leech observes, has thus been to add so many acres to the estate. But the most considerable work executed on these estates is the drainage of the extensive district alluded to, called the Wildmores. The extent and nature of this improvement is such as to deserve a particular and detailed description. Some adjoining properties have benefited by this work, and contributed to the expense of it, which was done under the authority of an act of parliament, but as almost the whole of the land belongs to the Marquis of Stafford, and the expense having been chiefly borne by him,
was at all times difficult to walk over them, it being necessary to select the hardest places to step on. They were covered with water after almost every severe rain, owing to which the inhabitants of the neighbourhood were subject to frequent attacks of ague. The adjoining lands, besides, to an extent exceeding six hundred acres, were kept in nearly a state of inundations.

The difficulty which occurred in draining this tract of land arose from the want of land, and from the river Teurn being pounded so high by the mill pools as to throw the water back to a great distance upon the land. The plan for draining this extensive district was extremely well conceived and judiciously laid out, in the double view of securing this object and of increasing the value of the farms.

The extensive district was laid out, and a plan conducted by John Hibbert, Esq., the first commissioner under the Act. The great object was to gain as much additional level as would create a run throughout the whole extent of the moorlands. This was to be obtained by beginning the cut which was to carry off the water a considerable way lower down the Teurn than the water had hitherto been discharged into that river; and a good deal below the mill-pool at Long, which occasioned this poundage. The original courses of the streams were straightened and widened, and they were still made to convey the water from the uplands, and to discharge them into the Teurn in their original direction. To prevent them overflowing the adjoining lands, and to cut off the effects of the back poundage of the Teurn on the upper moors, these brooks were embanked for the whole length of their course through the Wildmoors. These are technically called arga bunds. At the back of these banks deep ditches were carried, but in a more direct line than the course of the streams. Into these ditches the drainage of the moorland is emptied. The level which was thus brought from the river Teurn, from below Long Mill, was carried in a tunnel under the Shrewsbury canal, and was conducted below the several strines in siphon culverts, and thus communicated with the ditches described as having been made behind the banks which confined the waters of those brooks.

In some instances it has been necessary to construct one set of culverts over another, in order that the waters coming from the uplands may be kept in the several brooks through which they had constantly flowed, and that this water flowing from the uplands might not fall into the back drains; it being again explained, that the water flowing from the higher grounds is still confined to the original strines or brooks on an upper level; the drainage water alone of the moorlands being thrown into the back drains. Thus has a great additional level been obtained, and the whole of this district is now entirely relieved of water, and such a thing as a flood has not been known for years. This district is in some instances so flat, that the old course of the Preston strine, which formerly conducted the water of that brook in one direction, has with little difficulty been made a part of the drainage, and to carry the drainage water in exactly the contrary direction, a new channel having been cut for the strine. Taking advantage of this drainage, main ditches upon a regular system have been carried into all the neighbouring parts of the estate, thereby enabling the landlord and the tenant to execute various other improvements.

This district has been subsequently divided into regular enclosures, by great ditches, which fall into the main drains, and wherever it has been possible, these ditches have been made to serve this purpose, as well as that of a fence to the new roads which have been constructed across these moors. In one instance, one of these roads has been carried in a straight line for about two miles. On each side of this road, trees have been planted at regular distances, which will soon form one of the finest avenues in England. These moor roads have besides been all regularly under-drained by turf drains, which stand remarkably well. In the different ditches are placed flood-gates, to pound back the water during the summer, preserving the meadows in a state of perpetual verdure. The water is let off at least once in every fourteen days, and being drawn off with as much velocity as possible, it occurs and keeps clear both the ditches and the underground drains; - the mouths of these latter are all defended with tiles. The moorlands have been greatly improved by very heavy and repeated rollings and top-dresings; and their value as is to a farmer, in many instances, is fully doubled. This improvement has cost a very large sum of money; which was increased beyond what was necessary, owing to the inefficiency of the late surveyor belonging to the commission, which is now at rest. The drainage, however, has been so well put under a surveyor (Lewis), approved of by Lord Stafford in terms of the Act, and the expense is diminished, and the whole put in better order.

A very rapid improvement has taken place on these lands. In place of being the very worst part of the estate, they are rapidly becoming equal to the best and finest meadows on it. In order to shelter them from the blasts which come round the Wrekin, from the Welsh mountains, they have been intersected with various plantations. A plan of the Wildwood previous to [fig. 10844], and another subsequent to this improvement (fig. 1091.), will serve to give an accurate notion of what has been done; the whole being well worthy the examination and inspection of an intelligent agriculturist and improver.

(Loc. p. 226.)
10. **Livestock**

Cattle of mixed breeds: some dairy, chiefly for better to the manufacturing towns; some cheese, but not very good. Crops raised as stock, and sometimes rented for veal. Sheep in breeding flocks of various kinds. Stock in general neglected as to improvement; all sorts of crosses permitted, so that the historical breeds of sheep and hogs are not lost. Pig and bacon are much used among the poorer people, when they can procure them; therefore the sort which is to be fed will the least trouble to be prefared. A mixture of the Shropshire and Chinese rags, in this, has been found to suit bacon, and a cross of the wild breed for pork.

**Green,** reared on the commons, and sold to farmers, who fatten them on their stubbles.

**Turkey,** reared in large quantities by some farmers, and
dale, some parts rugged and others smooth, but

**7796. STAFFORDSHIRE.** 175,000 acres of hill on the whole more a mining and manufacturing county.

The Marquis of Stafford, Lord Anson, and the Marquis of Anglesea, are the chief improvers. Excellent markets for produce within the county. The manufacture of damask and Linen in the villages.

1. **Geographical State and Circumstances.**

**Climate.** Air sharp and cold, and inclining to wet; annual rains thirty-six inches; of Uppington, in Essex, nineteen inches and a quarter; Lancaster forty-two; of Ireland forty-two to fifty. Annual rain on the west side of the kingdom double that on the east.

**Soil.** In the north side of the county the bills arise, forming the commencement of a ridge, rising gradually higher and higher, and covered with meadow, where it is called Moorlands, then Pecks, then Blackstone Edge, then Craven, then Wensome; and then, on turning into two horses, called Chardwood.

1. **Propriety.**

Large estates, 10,000 a year, and many of all sizes, from that amount down to 240 a year. Attorney generally the manager, but some excellent examples, of ground from 5000/ to 50000/ a year managing their estates themselves; residing on them, and cultivating a part, and giving every encouragement to their tenants.

3. **Buildings.**

Some notable mansions, as Trentonham, Bemusden, Inglesdon, &c. Excellent farm-houses constructed on some estates, as Trentonham, Lord Stafford's seat, the majority in minor counties, had a farm-house built. A farm-house built at the family seat of the Amos, for a demesne farm of 2000 acres. The farm-house for Lunt, by S. Wyatt, of London, and consists of the farming steward's house at one end and a range of buildings along one side. A farm-house built in Northumbria by the Great North of London, for a water mill for the family and farm use, and in which is ground for the adjoining poor gardens, and a mast-house; the opposite side is ranged with cattle, and root house, store-room, stable, and other appendages; and in the middle of the yard is a water wheel, by which the water is raised, and goes through several sets of water-wheels, and covered with slate, with a boiler for heating hog-food, a cold bath supplied by the mill stream, for giving an occasional walk to the young pigs. In this building a number of pigs can live, fed on dairy refuse, blooded roots or vegetables, in the same yard, and supplied by the mill near a hand. At some distance above is the stack-yard and barn, where the farm-machines are worked by the same stream that afterwards supplies the garden, and turns the corn mill.

4. **Occupation.**

Farms of all sizes, from twenty-five to 500 acres; many considerable, with gardens, and containing comfortable and commodious accommodation for tenants. Those of 500 acres or more, have a water mill, and one of its kinds, and some of them, at the house of the steward, there are cold baths or washing-tubs, whose employment is one (fig. 1002), which contains a living-room, and working room, with a water-wheel, a brook, and a water house, which is allowed for twenty-one years. Little made by farming unless sold to elegiers, who drive them to Birmingham and other large towns which are nearer to the county. It is inferred that the farmers of this county are generally carried alive to market. There is not a single instance of an animal that has no previous prehistory of its being killed. But possums killed in the clover market, have several hours of previous suffering, and the burrow that has driven them from their food, is seen much increased thereof.

12. **Marshall's Review.**

Read generally bad; various smalls; trade of Shrewsbury, Telford, and Walsal well, used for clothing the mass in the West Indies. Some william and American rice numerous; iron, pottery, porcelain, glass, dressing cloth, woolens, buttons, linen, gloves, &c. An agricultural society at Drayton.
AGRICULTURE

This page does not contain any text that can be transcribed. It appears to be a blank page.
The character of the numerous cottages upon the estates is equally satisfactory, and without any interference with the manner in which a man manages his own business, that is, furnished, regular and decent in their appearance, and the work and conduct of the crops, so as to watch carefully over them, and where possible to promote the prosperity of the tenant and his family, now is done a potato garden can with advantage be added to their cattle, that accommodation is attended with the same advantages as before mentioned. It is easy to see that the necessity of allowing the poorer rates, except the children, to the tenants, who live in a great family, and even in this instance, the reluctance of every person labouring under similar difficulties. (Loc. in 1819.)

11. Line Stock.

Cattle. Staffordshire is known for the long-horned breed. The Staffordshire calf is generally considered a tolerable milker, as well as food for bacon. Sheep. Three sorts considered native breeds: the grey-faced horned, the heath sheep, with fine wool; the black-faced horned, with fine wool; and the white-faced horned, with long wool.

12. Political Economy.

Roads now generally good; numerous canals; several private manufactories of iron, hardware, cutlery, etc., and the trade of retail drapers, printers, dyers, jointed goods, potatoes, potters' ware, cotton cloth, silk fabrics, and other wares. Manufacturers sometimes carry on in the district, but for the most part in towns. Many thousands of both men and women are occupied in the trade of making nails. A considerable trade in currants, tobacco, small stuffs, silk, and the like, is carried on at Newcastle, and another at Lichfield. The trade of the iron and steel trade is large. It would be a wholesome plan for the Board to commence farming upon their own ideas, particularly as the iron manufacture is now so extensive, that there is no lack of skilled iron-workers. For instance, Lancaster, Westmorland, Cumberland, etc., by which our demonstration might take place in that way. As for the board, I am not sure that an improvement will not do for farmers in general. Such is the board's reason, in a most erroneous one.

797. WARWICKSHIRE. A surface of nearly 353,769 acres, mostly flat, but generally rich in soil and beautiful in appearance, and produces excellent wheat; but also many fat and fatish cattle; corn exists in the estates, but it has displaced more good to agriculture than many others, by introducing drainage. (Wedge's Report, 1794;

7. Grass. 353,769 acres in meadows and pastures, and 69,600 in artificial herbage. Formerly dairying common, and Warwickshire is said to be the most fertile county in the kingdom. It is not now as great extent of grass, but the grass lands are still much used, and will be so in future.

8. Gardens and Orchards. The gardens of the Marquis of Hertford, at Bagley, noted for its fine apples, are said to form a splendid orchard of any extent. 9. Wasteland. Much drained out in the northern part of the county; but it appears to be singular that the names of Tasey, Elvington, or their farms, are not once mentioned in Murray's report. Joseph Elkington's Priests, in Streaton on Dun- ford, 6 miles N.W. of Coventry, and after-wards in Birmingham. He died in 1806. He was a mere empiric practitioner, and knew nothing of genuine, the only foundation for drainage on scientific principles; less even than some of his contemporaries. A considerable drain on the report. Irrigation practiced in a few places on a small scale.

11. The character of the covert and the woods of the county, and the extent of timber, are subject to much variation. No particular breed of cattle; but as feeding is the prevailing practice, farmers buy in whatever breed they think will suit the market.

Sheep a good deal attended to; the large-potled sheep, or and small-potled sheep, are found in the county. The first cross of a Leicester sheep and Warwickshire ewe produces some of the finest Blood. Horses, the heavy black Leicester breed; a good many, in short, easy, rolling, and hunting horses. Pigs, the large Gloucester and Cornish breeds; a few smaller farms; great quantities sent to Birmingham and London.

12. Roads咂he roads are tolerably good in several counties; innumerable manufactories, especially for Birmingham, and others of the trade of making shoes.

Leashed land, per cent. mode of working; draining; drip- lit, and herbage crops, and better roads.

798. LEICESTERSHIRE. 522,240 acres of gently varied surface and fertile soil; distinguished for its pastures, and for the progress that has been made in the improvement of cattle and sheep. It is the county of Warwickshire. The principal head of breeding farmers. (M'Intosh's Report, 1794; M'Intosh's Report, 1813. Smith's Geological Map, 1821.)

To the value of every acre of such a farm, in addition to a fair rent being put upon the property.

The attention and influence of St. Stafford has been used in which the farmer would be benefited in carrying the comfort or advantage the good behaviour of his cottages, a considerable part of the produce, and the interest of the wealthier proprietors of these kingdoms, that it must ever dismay them in the operation of the benefits.

Schools, wherever they have been necessary, have been encouraged, either adding them by subscription, or by granting that the advice of the clergy of the archbishop and dean of St. Trinian, and the whole of the work and the nature of the services are directed by his ministers, assiduous to the parishioners, who are all in the best possible condition, and their success among the agricultural labourers is of a very great value.

The charter of this family is worth of an English nobleman. The parish during the reigns of the Margraves and Charles at Trinian, there is distributed daily to every poor child, that is in need, belonging along the road, and who applies for the same, a portion of good wholesome bread, in quantity sufficient to all the families, and of good quality, such as is given under the hand of allowances. Such facts are significant of the general condition of the poor from the residence of the great families of England on their respective estates.

The foregoing statement would have been given with some brevity, the facts being of a nature rather to exhibit and illustrate the charities distributed by the great families of England in general, than as being at all particular, the intention existing among the clergy, and those few families may help to explain to foreigners the nature of the charitable institutions between the richer and poorer classes in this country. These are the Lines End, and the charitable acts of those which compose the Staffordshire patterns, purity, education, and charity, as part of the cost of the estate.

Salt, chiefly clay or sand, marl, and limestone. The portion of the county, which at the time of the survey, was considered by the agents of the survey, and in the county of Coventry, and in the hands of the agents, they petitioned to be provided with this necessary article, which requires to be procured in great quantities, both for the purpose of building, for hearth or roofing of buildings.

Mortar, clay, lime, freestone, freestone, iron, blue flintstone, marble, bluestone, and soap stone, which the late Earl of Warwick attempted to provide for sale as a soap.

4. Occupations. Agriculture. In 500 acres, 1790 the average size on the cabbages, the cultivation of which is much increased. Farmers in this county are considerable as at the head of his profession, told Murray that in the best part of the county, the advantage of the Warwick stone derived from such a source; that it must do a great deal of hurt in the county, and that the stone, in being used in laying the drains, he declared himself to be perfectly satisfied with the stone, and would put to the use of farmers of clay and clay, which the late Earl of Warwick attempted to provide for sale as a soap.

Largest estate Stonelode, Chasms Lea, Eq., 45,000 acres; but a great variety of extent, and some curious and abundant timber.

4. Occupations. Agriculture. In 500 acres, 1790 the average size on the cabbages, the cultivation of which is much increased. Farmers in this county are considerable as at the head of his profession, told Murray that in the best part of the county, the advantage of the Warwick stone derived from such a source; that it must do a great deal of hurt in the county, and that the stone, in being used in laying the drains, he declared himself to be perfectly satisfied with the stone, and would put to the use of farmers of clay and clay, which the late Earl of Warwick attempted to provide for sale as a soap.

I. GEOGRAPHICAL STATE AND CIRCUMSTANCES.

CLIMATE.—Although the county has neither mountains or bogs to produce a cold or moist atmosphere, the soil is still clay or sand, no chalk; the pasturage abundant and of the best quality, and the long since drained.

II. LIVESTOCK.

Cattle. Although the breed of cattle in Leicestershire is umble before the last century, about which time Bakewell began his exertions, it is difficult to determine; perhaps there was not any distinct breed, with particular specified characters, whereby they might be distinguished from each other; but the produce never was equal to the supply of the country.

779. DERBYSHIRE. A mountainous and hilly surface of 692,880 acres of great variety of soils, but more remarkable for its mining and manufacturing productions than its agriculture. It is, however, at the same time both a corn and pasture county, and interested in the latter by the report of Farcy, in three volumes, is one of the most interesting and valuable of the county reports: it is an example of extrordinary industry and excellence in production, and will be read with great profit by every class of readers. Farcy, indeed, was a philosopher ahead of his age in which he lived. (Brown's Derbyshire, 1794. Farcy's Agricultural and Mineral Survey, 1819.

1. Geographical State and Circumstances.

Climate. Cold on the hills, but mild in the plains; in the vales hear frosts often injurious; no prevailing winds; rain about twenty-eight inches per annum.

Soil very various, chiefly calcareous.

Minerals. Lead and iron from those chiefly worked; also some zinc, ealmine, black jaco, manganese, sulphur, &c.; coal, limestone, clay, &c. Salt, freestone, gravel, gauding, brick, cutters, and cutters' stones, and a variety of others, both for use and ornament, as spar, &c. Clay in some districts, as at Over-marsh, is turned to use in pipes; in heaps, for the roads. E. M. Mundie, Esq. of Shipley, formed his镇 by a sort of bricks, made without the cost of brick-oven, to avoid the duty.

Ceramics. Where drinking ponds made by ponding and paving in the Gloucester-shire manner. An artificial pond dia-

2. Estates.

luminous, a century, concealed under peel, the head of which was ponded in the centre as a proof that peat is so new art. Stone cisterns, placed in the lines of newly cut thorn hedges, and small walled tanks, are found in them in thining pipes, as being cheaper, and perhaps more durable than lead.

Chatsworth, Kedleston, and some other noble stone man-

manor in this county; some good houses, covered with cement (known in London as Atkinson's), made from clay stones found on Lord Mambridge's estate in Yorkshire, and which Farcy considers, 1794, to be the best in the country. 1794. 1819. Lord of the London clay stratum. Grotto frequent, fitted up with the spar of the county. At Ashover a fine of chimney-piece, representing a section of the strata taken across the parish. At Chatsworth, and various places, the spits in the kitchens turned by water-wheels, are frequently made by a small lead pipe. Hair, turns, in covered boxes, placed on drying parts, and the lines whereafter a hair, being by a brazier, is thinned in the leadest hand, and turned; small lead pipes for boots and shoes, as at the Angel Inn, Oxford; boots and shoes are reversed on upright pins and taken by a stick, which prevents dust settling inside the boot.

Farm-barns in in other counties; a few good ones recently erected. Of all the farm-barns of various sizes that is that of the East of Chesterfield, at Bevles Park; it is of beam stone, slated, and furnished a general farm-yard, dairy court, and two-poultry courts, including pheasantery. Buildings in general roofed with grey tiles or of slate, in some cases, conducted down from patters by a light wooden rod down which the water runs as well as if it were in a spout or tube, and not blazed away, as it is in the case of the hedges and were there. Fire-proof floors made of arching them with hollow bricks; in some cases, cast-iron ovens by the sides of the times very common, and also iron cisterns for hot water; both these were originally brought into notice by the Griffin foundry, about 1778.

4. Occupation.

Farmers of small size; farmers rank higher in intelle-

ligeuce than those of most southern counties; nothing less than larger occupations wanted to make this one of the most improved counties of England. Best farmers also at same time machine manufacturers of miners.

5. Implements.

Swing ploughs and plait; one horse carts; good barrows (1800); weaving schools, for cropping off weeds among corn

1003

close, or rather under ground; weeding machines; threshing-

machines, for small rick stands; cattle crib, mounted on posts, which turn round, so that when the cattle have well trodden the litter on the two opposite sides, in standing to

eat from the crib, it turned half round for them to tread and dung, &c. in the opposite direction. (Farcy, 1794.) Plowmen, chaff-cutters, briars, slate cisterns as milk vessels, &c.

In setting out fences, less attention paid to separating the different sorts of trees than is requisite; fences frequent, and holes often made in them for passing sheep; to be closed when not necessary. Both with and without, or single and double, grown in calceolus, being the face of a newly planted hedge (as clay is in Norfolk), to prevent the escape of sheep. Young thorn hedges, with a northern aspect, do best, as the morning sun in spring injures the buds of those facing the south when previously covered with frost. Roots of thorns and other plants placed in set with success; old thorn-hedges effectively renewed by cutting off the shoots below the top, or by being laid on the ground and made there with vigorous shoots. Neatly clinched at Ashover. Magnificent hedges, and many soils found to suit the holy better than any other.

7. Arboreal Land.

On only fifth of the county in arable; formerly six horse

were generally employed in ploughing, now only two; turnips drilled in the Northumberland manner in various places; some wheat sowed; oats a good deal cultivated, and oats-cakes or Havy (Here) cake made, by pouring sour dough on a hot stone: a sprinkling of parsley soon set over to prevent cattle low-

ing; sides of oats stuck in with a spade, to leave no loose for grasses to root in.

Chesnouille "is cultivated to a very considerable extent on the limestone and cool strata near Ashover." The flowers are picked by children, dried first in the shade and then on a small malt, 10th around packed into bale, and sent to the London greenhouses; the crop stands three years, and then gets weedy and declines.

Hops cultivated on a small scale.

Walnut-mor (Genista tinctoria) infests old pastures, and is pulled to use in dyes, and dried and sold to the general views.

Yarrow (Achilles Millefolium) is in some places taken up, to be dried, and used for the dyes.

Valerian (Valeriana officinalis) in grey, and also elecampane (Fennula Helenium), lavender, peppermint, and rhubarb, on a small scale, in one or two places.

Teetree (Taber ciliatum) collected in various places, especially at the mouth of the three creeks, and ordered by druggists. Roses formerly cultivated for the flowers, but not at present.

8. Grazing.

Three counties of the country under permanent grasses (though it appears by the marks of ridges to have been formerly everywhere), and the application of manure has been of great help. Dropping of cattle and horses pastures upon themselves, which injures them more than any other implement. Fern and other weeds collected from waste, and dried and made bales, and their ashes made into balls, and laid side, to be used as ley for walkers, and kept free from the deserr我也hes decline with the frequency of enclos-

ures. When worms are engaged farming worm-casts in fields, the worm casts, with fresh and dry from the winnowing machine, which, stacking to the worms when they come out, gives the worm and prevent their return to their holes, till roads, &c. devour them.

9. Gardens and Orchards.

Garden flowers grown all at the principal towns, and few of the farm-houses and cottages without gardens. "Samuel Tickell, Esq. (the latter) keeps a professional gardener, and has three acres of rich sheltered land, by the river kang, on the Chealse side of it, where vegetables, flowers, peaches, and delivers all the useful vegetables and common gardens, which are laid out in his cow and milk work-people and tenants, and rends an account once a fortnight to the mill-agent, who directs what they have purchased from the garden from their several wages; the persons who receive it, and arrange it according to the season. But cannot but prove highly gratifying to those who wish to see the labours of a class rich and comfortably provided for from the fruits of their industry. Proper points, for drying, cleaning, and preserving garden-seeds and fruits, and his wool-carding and other like offices, are attached to the gardeners' house, and
Book I.

AGRICULTURE OF DERBYSHIRE.

1153

10. Woods and Plantations

A good crop of chestnuts, the produce of which is much in demand both for mining and agricultural purposes. Sir Joseph Belper, the present owner, has planted some forty years ago a new manner; first planting narrow slips of Scotch fir at the distance of ten feet apart, then intersecting them with rows of willows to leave the surface checked; after the Scotch fir are grown a few years, it is the intention to thin them out to one tree in a square yard, by which means the willows will have room to grow. Some judicious observations on pruning trees, and the propriety of the mode, pointed out by various authors.

Fir and rowan trees, sparingly introduced and well trained, are nearly all that fertile agricultural and ought to contribute to the natural growth of timber. Key-bearing trees, such as birch, will be found very useful, as they will bear berries, no longer increases much in timber, as the trees are cut down before they have grown to be desirable for females, or such as have both male and female flowers on the same tree. The use of the spur and poles of the oak as bark recommended, as practiced in Cheshire and South Wales; when collected, they should be immediately sent to a mill and crushed. As no complete seasonings kilns for tithe at Belper. Timber often sold by tick and sale, thus described: the voucher is a small piece in an envelope, and put in a gable; the owners do the same, and the wood is sold by the flat or bundle.

A Birch vine has been made from an open grove of about 100 acres, lately removed by railway, averaging 100 per acre. Thirty or more are tapp'd in a season, about six or eight inches above the ground; in March. A piece of bark, about three quarters of an inch thick, is cut out with a gouge, and the wood penetrated an inch or more; an iron spout (fig. 1005a).

is then driven into the bark below the hole, which conducts the sap, or sweet juice, into the vessels of the tree, and from four gallons in a tree, not more than half a pint. The wood is sold at sixpence a gallon, to those who make small wines. This vine has been tried for about ten years, and it proved (not belted), it may be kept a month before it is made into wine.

In making the wine, two pounds of sugar, and a quarter of a pound of Malaga raisins. The wine is generally made from white wine, when it has been boiled about an hour, until it is observed to grow clearer, when it is set to cool, and when about the same temperature as the liquor in which it is to be spread with yeast, is put in, and for four days suffered to work freely.

Ten different breeds of cattle at raising as before, and about an ounce of linseed to every twenty gallons is added thereto. The wine is spread in two or three weeks, is ready for close bunging down to remain for three months, when it should be bitted off, and in two or three weeks after it is fit for drinking, but is better for a spring long.

11. Improvement.

Mill-ponds or hot land very thick spread has its inestimable properties; and it would seem such limes may be used where a stimulant rather than an addition of calcareous earth is required. Lime overburnt on its and runs together in a separate, and becomes useless; the consequence of too strong a fire being applied to the lime or manure. Miga planted on the dried mud of limestone beds is used instead of lyme to raise house mills in use; they are composed of ratchet-like from wheels and rollers, between which the backbones of horses, with their adhering ribs, pass with facility, and are crushed into small pieces; the bones collected in London, from the churchyards and other sources; seven quarts are drawn at each strike, and the corn is manufactured into a valuable manure. Importance in draining of bearing in mind the difficulties of such produce, and the discharge and spring drainage, and upland and drainage.

12. Live Stock

Cows used for dairy the prevalent stock in Derbyshire; no particular breed; noticed nine breeds and nine crosses of the different kinds of cheese, and old with more than artificial grasses. In making the cheese, the milk is taken from the willow trees within the reach of cows, to prevent their eating them, and tasting the butter. Milk as thick as cream, and with few specks. When in some places in late slates trowsers, carried home in suspended sacks. (fig. 1006).

Homo. Those of Derbyshire ranked next to those of Leicester, for being stout, bony, and cax-reneged. 4

1106

Asses in considerable number used by the smaller manufacturers, and in the smaller districts, on the main road.

The Earl of Chesterfield supplies his table with delicious cooking pigs, of a fortnight old, from Mt. Oatheye saw a plan of sharing off the great quantity of horses, to prevent injury from the vines, to prevent digging, recommended. Tethering by the neck also suggested for eating down sturdy herbage crops. A breed of pigs, to be raised as those fixing down, Palomino-hairless man-trap. (Tomp. Soc. A.A., vol. xxviii. p. 185.)

Poultry. The Earl of Chesterfield's poultry yard at Bredley, perhaps as complete as any in the kingdom. The roosting-house is well equipped, with covered places for the ducks and geese under the roof, and the whole is constantly kept strewn with fresh sawdust. The sitting-house, and which serves also for laying, is furnished with flamed polished copper sauce-stands in front. In the feeding-houses, the front, partitions, and floors of all sorts of work, the whole being kept for cooking. In Tanday the cockerel converted into a methodic meeting-house. Eggs preserved in the shell and turned into a fresh preserve; this being the main essential in preserving eggs, whose yolks suitable when left unmoved, and come at length to the shelves, when rottenness almost immediately commences.

Here kept in various places.

Fish. Certain ponds in Sts. Thomas Windsor's Humlocke's Park, in Wincobank, near Chesterfield, are remarkable for excessively trrated male carp and tench, which are found the prefer for small fish to other species; feed on the root of Peas, &c. When waters are much impregnated with lime, the eggs of gudgeons and ducts that frequent them are so much thickened that hatching becomes difficult.

Hens. At Pleya a fine breed of black fowls; round Wingerworth for milk and egg fowls is kept for cooking. In Tanday the cockpit converted into a methodic meeting-house. Eggs preserved in the shell and turned into a fresh preserve, this being the main essential in preserving eggs, whose yolks suitable when left unmoved, and come at length to the shelves, when rottenness almost immediately commences.

Here kept in various places.

Fruits. In the vicinity of the Agricultural Society at Derby, as by most others in the kingdom, for long and meritorious hired of the day service. A distinguished performance for preserving the quantities of 600 work, or earned the most money by such at fair prices. At the beginning of the present century, it was culplified, taking the laboured work at two shillings and sixpence per day, that he must work for four and a half times as many days to earn the same quantity of food, as from three to five centuries he could, when his daily wages was from fourpence to twopence per day, this being also diminished by the many idle saints' days which the church of Rome imposed on the people at the earlier periods.

14. Political and Historical.

Various canoe roads formerly made, through the influence of Joseph W., Esq. of Mochlen; those in a very in different state. and illustrate the absurdity of the principles on which they are supposed. To level roads, there was const of a piece of boxwood eleven inches long, and a half broad, and one and a quarter deep, with about a foot of width above the top, at each end of this level, several sorts of strong whiped was, fasten'd. In using this instrument, a labourer was placed on each side of the road, having the cord in his hand, which they pulled very tight, and stealing against each other, and thereby made the bubble assume the middle of the road, as in this way the poles, the ends of the string were led into one of the road. Some remains of watch-roads (5351.), but nothing to justify any desolation from the break form similar mode of excursion with straight or even surfaces as to length. The road between Ripley and Little Eaton, who, washing or irrigation has been adopted as a mode of care (Coom. B. Aq. vol. i.) was much inferiorly deep, being forty.

In Manufacturers Derbyshire ranks next to Lancashire, Staffordshire, and Warwickshire.

15. Trade, Agriculture, and Animal Products of the county.

Blanket-weaving, and scouring.

Bee-crushing mills.
Butter.
Bouillon-molds, of horn and bone.
Candle-making, of tallow.
Carpet-weaving.
Cane.
Curriers or leather-dressers.
Fiddle-makers.
Fishing-nets.
Glaze-makers.
Leather mills, for oil'd and chamois leather.
Moo, beef, lamb, mutton, pork, veal.
Stone-farce.
Skinners, or leather-dressers, chamois, &c.
Smoothers.
Stockings, of worsted.
Tannaries.
Woolen-cloth factories, yarn spinning, weaving, and cloth dressing.

2. Textile, &c., depending on Vegetable Productions of the county.
Basket and wicker making.
Bean or broom clover.
Boat or large building, for the canal 

3. Textile, &c., depending on Vegetable Productions of the county.
Charcoal burning and grinding.
Charcoal, for graining it.
Corn, barley, oats, peas, wheat.
Hoops for casks, of wood.
Malt-makers.
Mattresses, chair-bottoms, &c. of straw.
Millers, flour or meal makers.
Nuts, or riddles for corn.
Shelling, or oat-nail mills.
Timbers.
Woolen spinning mills, for wool, bobbins, bowls, cheese-vats, dishes, 
tool-handles.

4. Textile, &c., depending on Vegetable Productions of the county.
Beech-boarding.
and grounds.
Calico-printing.
Calico-weaving.
Cammie-weaving.
Candle-wick, hemp or bung spinning-mills.
Cotton-spinning mills.
Dye-houses.
Flax-spinning mills, linen-yarn mills.
Flax-weaving, hemp-bags.
Hemp-bag spinning and weaving, wool-bags, &c.
Lace-weaving, or warp frame-lace making.
Lace-working, or needle-working of frame-lace.
Linenspinning, sheathing, checks, &c.
Muslin-weaving.
Nightcaps, of cotton frame knitting.
Poorhouse spinning, string, twine.
Paper-making.
Paper-kinking, cords, hatters.
Sacking weaving, hemp-bags.
Nail-cloth weaving.
Stocking-weaving, principally of cotton, some of worsted 

5. Textile, &c., depending on Mineral Products of the county.
Bakstone making.
Bottles, of iron, for steam-engines.
Brick-making, building, draining, fire, paving.
Building-stone, for pavings, and aggregate, for buildings, slate.
gable-stones, paving, redding, grey slates, or tlestones and black pozzolana.
Concrete, or sheets.
Cannon-casting and boring.
Chains-making, iron and cast-iron.
Chinestone, or white potter's chest-pits.
Cutters and troughs of stone, to hold water.
Cly-pits, brick, china, fire, pipe, pottery, and tile.
Coke-pits.
Coal-burning.
Copperas-stone, brasses or pyrites pits.
Fringing of iron.
Grind-mills, blade-mills, grindstone mills.
Grindstones.
Gypsum, alabaster, plaster.
Hackstones, mills, forge, patina, planishing mills 

6. Textile, &c., depending on Mineral Products of the county.
Ilmenite, or iron sands.
Iron-forges and furnaces.
Ironstone, building in Pennsylvania, and elsewhere.
Lead-mines, or veins of lead ore.
Leather, or the production of.
Lime-kilns.
Lime-mills.
Lime-stones.
Lime-wasters.
Malt-kiln plates, of perforated cast-iron.
Marble quarries.
Marble sawing and polishing mills.
Marl pits, for manuring.
Marl, or lime-stone, quarries.
Nail-making, of cast-iron.
Nail-heads, or a clasp (or carpenter's), and spikes, &c.

5. Textile, &c., depending on Vegetable Productions of the county.
Rolling and sitting mills, for iron bars, plate iron, nail rods.
Rolling-mills, or polishing earth.
Sanct-huts, cast or founders' house, floor, masten's mortar, 
sieving, and the mortar-stick sand.
Saw-factories, for stone and wood, also with circular saws.
Screws, carpenters', for wood.
Shears and knives, for sharpening scissors, knife-blades.
Shovel-board, milled lead, rolled lead, Common sheet-lead is 

6. Textile, &c., depending on Vegetable Productions of the county.
Axes, hatchets, bills, adzes.
Brass foundry.
Brindle-hits and buckles.
China-clay.
Chisels, gauges, plane-irons, and other edge tools.
Clock and watch making.
Colour-grinding mills, paint.
Comb-making for makers, for the cotton-spinning mills.
Cutlery, knives, forks.
File-making, razors.
Flint diamonds, for pottery glazing.
Frame-smiths, stocking-loom makers.
Gunstock-making.
Gum-powder-making.
Hats and caps, of flax, and cotton, for hatters, travells, &c.
Implement makers, agricultural tools.
Malt mills, steel mills.
Manganese, for linen clothes.
Mechanics, machine, tool and engine makers.
Millwrights.
Needle-making.
Round-iron, or smooth-edged.
Sieves, of cast-iron, cemented to steel.
Sidewinders, for clothes.
Smatch makers.
Spades, shovels.
Spades, for steel.
Shingup of cast-iron, cemented.
Tin-plate workers, tinners.
Wallows, for clothes.

Worsted machinery, maker, for the worsted spinning-mills.
Wrought iron, that is to be used in the manufacture of the many of the cotton and woolen productions above mentioned are separately of small importance and cannot be exchanged for or without an export trade from the county, yet, taken in the aggregate, they must be admitted to prevent a most flattering picture of the varied and 

B. STATIONS OF AGRICULTURE.

Education.
Among the labouring classes, the reporter observes, is better attended to by the inhabitants of the adjoining counties.

Agricultural Society.
It approves of the great attention paid to bringing up children in the common school; in industry; and cough, as the "great and desirable end, their complete emancipation from the moral slavery and poverty and dependence, and its attended 

Mineral stations.
It is stated, and we believe, that the writer can please every reader 

for the most part; and there are no free, we hope, who would not be grateful with his heart, and would be glad to see the nation, and as universal and 

Without the Thames, the present is the full blossoming of the country labourer.
Throughout the country labourer, and call loudly for legislative interference and general sympathy.

Abolition of Improvements.
There are leading societies in most of the principal towns: to be regretted that the funds of the board of agriculture do not encourage the circulate the cheap agricultural books; agricultural 
books have as large a sale in Berkshire as in most other counties.
A "Farmer's Magazine," and a great number the "Farmer's Journal," which, if the stamp duty was removed, would cause a great increase in circulation, is an 

farmer's society at Berkshire, since 1794; a society for fat wether sheep at Leptons: at Hayfield, a society of mintam sheep keepers, since 1790. A list given by G. of ninety-three agricultural societies in England and Wales. The late Earl of Chesterfield, who granted £50 in premiums annually to his tenants, as recorded in the Farmer's Journal, 15th December 1813, and 15th January 1816.
AGRICULTURE AT LINCOLNSHIRE.

780. NOTTINGHAMSHIRE. 485,000 acres of uneven or hilly surface, in great part a sandy soil, and more a corn than a pasture county. It contains the Forest of Sherwood, the only one belonging to the Crown north of the Trent. This forest was once celebrated as being the scene of the adventures of the famous Robin Hood. Very little wood, however, now remains, the holding which the forest occupied, and is, besides, above a fourth of a century old, unproductive. [Lowe's Report, 1798. Marshal's Review, 1812. Smith's Geological Map, 1821. Edin. Gaz. 1827.]

1. Geographical State and Circumstances.

Climate, remarkably dry. The main crops are oats, barley, and clover grass, and the remainder a lime and coal district.

Minerals. Stone, lime, coal, gypsum, and marl.

2. Agronomy.

Estates from £4,000. a year, downwards.

Farm houses contain more gentleman's seats in proportion to its size. Alston Grove, a noble residence; the garden for the purpose of orchards, the view from the Watson Field Park contains four thousand acres. Newstead Abbey, celebrated as having been the residence of the Prince family, but now sold and occupied by the Worksop Minster, eleven miles round. Welbeck Abbey, the scene of the horticultural Improvement in Spilsby, is remarkable for its extensive views. Welbeck, Spital, Newstead, &c. are varied and wooded, and command fine views of the county.

There are large tracts of good sand, loam, chalk, peat, and considerable extent of mixed soils.

4. Improvements.

Plough with wheel center used in the fen tract as in other counties. The farmer's yoke being considered a right, but ploughing among stubble and couch grass-that the word one should be given to the farmer's yoke, and that the farmer's laborer shall be the subject of the law. It is, however, a remarkable fact, that the area of cultivated land in the eastern counties is much greater than it was a hundred years ago, and the amount of land being raised from seed on the Welbeck and Climber estates; the ground is improved; and the surface more elegant. There is a high proportion of western farmers, and every new improvement is followed by a second. For every new improvement on the Welbeck, the North and other towns.

5. Occupations.

The greater part of the population is employed in agriculture. Their professions are very various, and the general result is satisfactory. Many of the farmers have a larger proportion of their farms under cultivation than they formerly had. The new method of ploughing is gradually becoming a general practice. The cost of cultivation is decreasing in every part of the county. The income of the farmer is now larger than it was a hundred years ago, and the amount of land being raised from seed on the Welbeck and Climber estates; the ground is improved; and the surface more elegant. There is a high proportion of western farmers, and every new improvement is followed by a second. For every new improvement on the Welbeck, the North and other towns.
STATISTICS OF AGRICULTURE.

PART IV.

1. Geographical State and Circumstances.

Climate. Favourable both to cattle and to sheaves, redeemed from deep falls of snow and long-continued rains; highest point in the county supposed about 800 feet above the level of the sea, and there is nothing mountainous nor bog. Denham found that the wheat harvest generally commences about a fortnight earlier than in Pershore.

Nest. Great pastures on a caledonian bottom, limestone, schistus, or slate, and the clay of the sandstones. The surface of the clay, may be classed as strong and deep loam, light thin reddish soil, thin sandy loam, and the sandstones are marl.

Minerals. Clay, limestone, marl, freestone, and slate.

2. Buildings.

Almost wholly in large estates; thirty-seven of above 5000l., half of which are from 5000l. to 10,000l., managed by seamen.

20. Improvements.

Thus writes to him:—"In my opinion water-rising renders the quality of the heathland and the land worse for the process. Where land is tolerably producive, and in a situation where a quantity of grass food is not required, I should certainly not advise it. I think the land may be turned to better account without it. But I think there are many situations, particularly on grass land or sward, where it may be very advantage- ous; the produce, by such means, is certainly much increased, and, in some instances, considered larger when this operation would be produced. Though the produce is increased, yet it is increased by a very few acres, so that it is worse, and mixed with rushes and plants, that cattle frequently refuse to eat it; and when it is eaten, the appearance of the cattle proclaims it. On the average of the hestead nature, it was formerly an advocate for irrigation, and am still on such soils as have been below curtailed; but I have had several opportunities of viewing several water meadows which have been of the same kind, yet they have been operated on in both the heathland and land, I have been obliged, in a great measure, to alter my opinion."

100. Geographical State and Circumstances.
1. Live Stock.

Cattle of the county, the long-horned breed: but various others introduced for fattening and the dairy.

Sleep of various breeds; a good many new Lexington.

A variety of country cattle; bred for the coach, the army, or large wagoners. Blood horses formerly bred, but left off, as the breed of the gentleman is unusable.

Roge, a breed between the Berkshire and the Toulouse.

2. Poultry.

But red, but many handsome bridges; some canals. Manufactures — shows for the army and navy, and exportation; of which one has: wares, clothing, and every small industry.

Several small friendly societies for the promotion of the arts, justly rated 

Ecology is one of those which was founded in 1738, meets at Longport; and is used for purchasing land on approved.

Horses, being ready, and easily to be obtained at a very moderate price, 2 s. 6 d. and the like, being for the town, and the township to the pasture, &c.; woods which are private and entire property are better managed.

3. Grass.

Great part of the country under old pastures, including some meadows, chiefly applied to the feeding of horned cattle; cattle generally made fat on grass, and finished by feeding on turnips, peas sometimes on turnips, by burning. Grazing much better than that observed in the forest.

8. Gardens and Orchards.

A particular species of plum grows at Shorborne and in the near neighbourhood, called the "wince." It grows well both on gravel and limestone, is hardy, a good bearer, and answers upon any soil; but on heavy land, not so well. As it is good, on any as on limestone or gravel. On a strong deep land, the trees ram too much to a wood, and do not bear fruit in proportion. These plants blossom better than any other sort, and are propagated from suckers. The fruit sells from 1s. 6 d. per peck, to 2s. 6 d. when crack'd and damaged.

They are easily hurt by rain. Plants to be had from most public nurseries, and private growers; in which they should be planted on a layer of lime or chalk.

Much oak and ash wood grown, and a ready market found at the shipping and manufacturing towns.

10. High and Low.

Two hundred and sixty-five thousand acres capable of cultivation.

11. Improvements.

Warping the most remarkable; ably described by Lord Hawke, and by that of Landworth.

12. Live Stock.

A great variety of breeds of cattle and sheep in use, but no one generally a good one. All kinds of land, when milked twice a day, a cup full of dissolved nitre is put among eight gallons of milk, whose removal has been found the best way generally used in draught, not many beast excepting in the east-end part of the district; sort in use among the farmers a small herd.

13. Political Economy.

Many great and useful works; various canals. Numerous manufactures of shawls, calicoes, flannels, and every branch of manufactures. But when Chaucer's time; at Rotham, run-works. These and other manufactures the cause of the wealth of the West Riding.

Leases, division of commons, enclosing of wastes, better rotations, &c.

7806. NORTH RIDING OF YORKSHIRE. 1,11,187 acres of high and extensive moor lands, chiefly remarkable for boulders and heath, particularly those sort known as Cleveland.

Smith's Geological Map, 1821.

Rarely with two rooms; damp and unhealthy dwellings. Close walled roads used, as in the poor parts of Scotland, and very unhealthy.

A. Occupation.

Farms on the v. e. or small, many very small; farmers sedentary, industrious, and laborious, many of them have been educated, and educate their children. Few leases.

B. Improvements.

Rothwell or Paget's plough; bay spear for drawing hedges has together with a horse and a simple sort of cart (fig. 188, a) in use, formed almost wholly of oak, the bow, &c. The heads of it are broad (d); which entirely of wood (c); when to betensor, the horse is harnessed, and does not touch the others. Abernethy's plough, or, as it is called, Malvern.

It is the v. e. of York and Riding. About Cleveland and the moors much less. Culture and rotations as in the West Riding. Rotten ploughs and horse; often mixed with wheat, and is called Malvern.

Tobacco much cultivated a few years prior to 1782 in the v. e. of York and Riding. In the latter district it did not excite the notice of royal authority; and was cured and manufactured by a man who had formerly been employed upon the tobacco plantations in America; who not only cured it but pro-
Horses. This Riding long famed for its horses, particularly those of Cleveland. In the northern port of the vale of York was what is known as the 'Yorkshire Coach,' a full-blooded coach horse, very strong and active, and well adapted for either prolonged journeys or the utmost speed. All the other districts of the country have some breed; on the western moors of Scotland galloppers are put to the stallions of the country, and 'rear a hardy and strong race in proportion to their size.' Before the wars, they were much bought and sold, and sent to the West Indies. Some farmers do not breed, but buy rots and work them till four or five years old, and then breed for the first year, and sell them to the London dealers for coach horses.

The farmers who breed horses, generally breed from those mares which are employed in the business of the farm; these are often worked until the very time of foaling, after which they have usually two or three weeks rest, before they are again taken to work; the foal, during the time the dam is working, especially whilst it is young, is shut up in a stall; and if the practice of some, before she is suffered to go to the feal, after returning from work, to bathe her colder with cold water, and as much straw as possible to keep the mull from it, to prevent the milk, which may have been beaten by the mother, from hav- ing any harmful effect upon the foal. Some continue this practice as long as the dam is a milk-producer. The first has got sufficient strength to travel along with the mare, take it along the roads, and frequent the markets, and, from an opinion, that by the milk being frequently drawn, less danger of it being tainted, of possessing any quality prejudicial to the foal.

The general time of foaling is about May-day (from which day the age of all horses is reckoned), and that of weaning about a month, when they are put into good arable, or, the best pasture the farmer possesses, as long as the weather will permit. If there be sufficient food, and, on the approach of winter, have a little of the green hay, or Alfred, a stable, or hovel, that they can go into at their pleasure.

The foals are usually gilded in the spring following, and in summer are allowed only as market pasture, the next winter they are to live in the fields, or in the straw-yard, except they are intended for the horse market, which is frequently expected of those of a strong kind; such are rather better kept as the time of labor, or the time of the market, and are only put to light and easy work, and generally work only half a day at once.

The foals are one year older, before the operation is performed, and find that such treatment does not make the colt hardier and handier horses. The foal always receives a great check by being weaned, which it does not well recover before it gets the fresh pasture of the following summer. The foals which are gilded at one year old receive a second check, at the very time they should begin to recover from the first; whereas at two years old, and appear to be in the best condition for the operation, and recover at least as well as the younger animals, and are much better qualified for the keeping of the preceding year.

Economic Value. - The market horses which are sold for the London market, if for the carriage, are chiefly hay geldings, with bond's on their ears and faces, those which have much white, with chestnut, brown, and some piebald, coloured horses and mares, generally do not bear an equal price in the London market, for the common and better horses are more sought after by foreigners, and eagerly purchased by the clergy and country gentlemen, or by any of the classes of this country, who carry them to the foreign markets, and ultimately obtain a price equal to that obtained for those sold at home by these means of exportation, contrary to the notion received but ill-founded opinion, has a strong tendency to reduce the price of the best horses which are sold for the home market; and since as many fillies as colts are naturally bred, and one horse in twenty makes, therefore at least will there be more horses for the home market, or be of some other colour than that which is seen in great abundance at the time, if the breeder had not a market for those, which appear to be the two thirds which are sold unmanipulated, he would be compelled to put such a price upon them, which, as an event was expected to be the house market, or variable taste of the moment, it would pay for the other two thirds; from which it will be seen that the breeder would not be unable to dispose of them, without the inconvenience of inadequate prices. The consequence naturally flowing from this would be that the price of horses used at home would be far greater than at present, when often, and, perhaps reluctantly, the breeder keeps nearly as good a price for the horses which would otherwise be sold, and disposed of, as those sold at home, valued at home.

Roads. - Roads were kept in one or two winters; in one the silver grey is kept, the skins of this variety being worth double those of the grey, not used for feet like the common skins, but dressed as furs and exported to China to be worn by the Mandarins.

1. Geographical State and Circumstances. - The climate is never so severe as to produce any specific harm, or no man pre- tended title to it (it being a detached parish), is a grant of 1200 acres, which was given to Whits and Scamborough, at various places in its neighbourhood, and in the course of time, when the coast was burnt and embanked, it was originally about two miles from the shore, and many acres are still lying which, if not embanked, would be washed away by storms between the sea and the mainland, to which it is now united by a

5807. EAST RIDING OF YORKSHIRE. 819,900 acres of moderately way surface, intersected with numer- ous, deep, winding valleys; not remarkable either for its arable lands or pasturage; but productive of horses for the coach and saddle, and of the excellent Holderness breed of cows. (Leatham's General View, 1794. Strickland's View, 1812. Marshall's Ruins, 1812. Smith's Geographical Map, 1821.)

Sunk Island on the Humber is a modern creation by that estuary. It was formerly a part of a sea island, but became connected with the mainland, and was afterwards detached from the latter, and in 1818, a year, a chapel and several farms were erected on the island.
AGRICULTURE.

Where white the certain near two liar occupied average bear have larger have cent

The the less the the average trifling occupation. the

Inhabitants generally, excepting above water for a few days at neap tides, no plants take possession of the surface; when vegetation can go on, the first plant which begins to grow is usually some weed, and next the moss, which in some cases quite covers the surface with a close short sward. A few sheep are occasionally put on it when not too much disturbed by the wind of the spring.

In lying land to grass, canaway and pasture sown among it some, to be filled with the health of the sheep.

Gardens and Orchards.

Almost unknown, excepting among the higher classes; farmers rarely use them. It is remarkable how well cottagers cultivate their gardens with more care than the farmers.

Woodlands.

Of no great extent in proportion to the land; extensive plantations exist in the western parts, but none are dense.

Improvements.

Holkerness: an extensive tract of the kind, on the east side of the river Humber; it extends over nearly 12,000 acres, and is managed by commissioners.

Live Stock.

Holsteins, dry and of large size and abundant supply of milk, peevish universally. This breed is supposed to have been introduced from Holland about a century ago, and is now extensively grown and improved by artificial management. The late Sir Charles Strickland, the greatest modern breeder in the district. Breed called the Lincolnshire breed, is in some places somewhat different from the breed as far as the quality of the animals is concerned.

Horses for the coach and saddle, the grand branch of breeding in this Riding, and at many places more produced, in proportion to its extent, than any other. It is supposed that the breed has been of late much degenerated, owing to the intermixture of the Thoroughbred, which was never pure, with the heavy Holstein breed, which was introduced, by which, though good saddle horses were produced, the coach horses were lost. This error discovered, an opposite and still more pernicious one was produced by the introduction of heavy black stallions from Lincolnshire. These produced a breed which could not get rid of for several generations. In breeding, some estimate the foal while sucking, and think it is preferable practice to that of the North Riding.

Rabbits.

About twenty varieties, containing together probably 10,000 acres.

Political Economy.

Not more than 200 miles of turnpike road in the whole Riding few of these good, and the green roads and lanes very bad; manufactured leather, glass, lead, paper, pottery, etc., Acur. at Hull. Wholesale and Spanish-white for whitening are the chief manufactured goods. Holstein cattle, and even the best of the Teeswater breed, are not inferior to those of other districts. A great quantity of good menhaden is exported from the river, reduced to meal or oil, and sold in various parts of England.
or salt sulphur spring near Durham, and another on Lord Durham's estate, with public baths and dressing-rooms. Various others of less note.

2. Property

Largest estates, 30,000/ year, to 22,000/ a year; several from 18,000/ to 50,000/, from which they descend by regular gradations to 1,000/. These Messrs. Collins, Mr. Charles and the Rev. Alfred Johnson by proposal; but the general mode is to ask a rent, and treat with tenants six or seven months before the existing leases expire.

3. Buildings

Generally of stone and slate; cottages of one story, covered with thatch or tiles. In the west of the county, chiefly of brick. The smallest farm-houses contain their principal family, and the rent is only 3/ an acre.

Largest farm about 1000 acres, greatest number from 150 to 500 acres. The larger farmers almost only those who have manorial property, being of the lord of the manor and charge first led the way, and have been followed by Messrs. Collins, Mr. Charteris, Mr. G. R. Eden, and many others. By their exertions and judicious selection of stock this district will be largely benefited.

The number of small labouring farmers greater than their servants, being generally employed through the season, are at liberty four or six o'clock in the morning till eight at night; and in every other season, excepting winter. It may truly be said "to rise early, take rest late, and eat the bread of carefulness.

Loans, three, five, and seven years, excepting church and corporation leases for 21 years, and lives. These farms let for short terms remain stationary; as no prudent man will lay out his money in improvements, for which, when completed, he will not be reimbursed by an advance of rent, proportioned to the improvement he has made.

5. Implements

Swing ploughs of the Rotherham kind; of late the Small's plough with a number of good improvements, and in many parts now (1850) the improved forms of Northumberland and Beddington.

6. Enclosing

On dry soils hedges are frequently planted on a raised margin between the fields, and the height twelve inches; a small ditch is cut on each side to make a water course, and the quays are planted in the middle. In this mode the land may be ploughed at any time in the year. As the thorns are grown to a sufficient height, almost close to the hedge. With this mode of enclosures, if five years old, every other stem is cut clean off, within two or three inches of the surface, and the remainder is cut off in a hand-hoe fashion; then stakes of thirty inches high are driven in at proper distances, and the splashing-stems, having a slight cut on one side to make them stand upright, are planted in the wounds amongst the stakes at an angle of about twenty-five degrees, and a single edger is wound round the top to keep the stakes tight.

7. Arable lands.

Ploughing generally well executed, but in some places the scabou prevents sufficient depth of furrow, i.e. six inches. The labour in the north is much inferior to the south, partly from the land being commonly arable, and partly from the absence of turnips in many places. With regard to Durham, the standing turnips are kept in feeding cattle, not in sheep. Men, taken on in this district, are much more judicious 

Potatoes in the village of Hanley have been the principal article of diet in the eastern part of the county, and are esteemed well for families for eighty years; they are very particular in having good sets, each with two eyes; use redish or pink sorts, placing them from three to eight feet apart; the tubers are kept in cellars, and not allowed to come to the surface of the earth; they may remain in a cellar from one to two years without injury. The best potatoes are those which are preserved in the cold, and are generally kept a year in a dry place, some in the cellar, for in this manner they are kept in a better condition, and improve much. The highest weight of potatoes sold in the market of Durham is about 74 pounds, and the weight of the average piece is about 3 pounds.

8. Pasturage

In the west the turf has been improved by the introduction of tins, with projecting letters and figures. They are two and a half feet high, and fixed on an oak post, four and a half feet from the post, to which they are fastened in the following manner. No iron railways, and no public roads or canals.

Manufactures.

Wrought iron foundries, glass-houses, potteries, and woollen-factories. Cotton, flax, and leather products are produced, and the county has a large share in the export trade.

9. Timber

The oak and ash are chiefly the staple products, and the sycamore and lime for carving. The oak is much inferior to the ash, and the sycamore is of little value. The sycamore is chiefly used for the joining of doors and windows, and is extensively used for the roofs of barns and stables. The ash is chiefly used for the roofs of houses, and is extensively used for the roofs of barns and stables. The sycamore is chiefly used for the joining of doors and windows, and is extensively used for the roofs of barns and stables. The ash is chiefly used for the roofs of houses, and is extensively used for the roofs of barns and stables.

10. Embankments.

Buildings, embankments, and new roads were made in the 1740s, and about 1500 acres secured between that period and 1806.

11. Foreign Trade

Short-horned cattle. The famous Durham ex bred by Charles Colling of Kellam, in 1796. See the description of the Durham and Leicester breed: stock bred, reared, and fed in the most scientific manner, especially by the large farmers, as at the villages above.

12. Political Economy

Turnpikes roads first made in 1742; materials, whitestone, and sandstone. Reaiford, Chilton, and Eamont have likewise excellent stones. Materials are broken sufficiently small: they are also in good repair, and generally kept open. The roads and bridges are made of cast-iron, with projecting letters and figures. They are two and a half feet high, and fixed on an oak post, four and a half feet from the post, to which they are fastened in the following manner.

Manufactures.

Wrought iron foundries, glass-houses, potteries, and woollen-factories. Cotton, flax, and leather products are produced, and the county has a large share in the export trade.

Agriculture of Cumbria

4. Occupation.

Farms generally large in the north, some from 2000 to 4000 acres, many of the small farms from 50 to 200; from 1600 to 1800; and 1500. A year. The capital necessary for such farms entitles the farmer to a good esti-
mated value, and on this they put a spirit of independence and enterprise, that is rarely found amongst the occupations of farmers. To short leases, not minding being open to conviction, they are ready to take advantage of it, and adopt every improvement that can be learned in other districts; for this purpose, many of them have travelled not only in this country, but in the

5. Improved Land.

Of the most approved kind; and some of these, as the plough, drill, horse-box, &c. owe their chief improvements to the laborious efforts of farmers. Where the pruning shears recommended as preferable to the cutting edge for cutting hedges. They consist of a strong sharp knife, six inches long, moving a little two square-ended edges; the upper handle is two feet six inches long, and the other two feet three. See Angelopedia of Gardening, April 15, fig. 142.

Size of farms varies with the size of the farms; in some parts from two to six or eight acres; in the northern parts, where the farms are large, from 20 to 110 acres. Much land, such as heath or moor, should not be reckoned on the same as eight, and, upon good land, a foot. Quicks four or five years old, with strong cubs, does, and a calf or two, and a man and a younger and smaller. It is a custom in some parts to chip ploughs, and to keep the work up to the end of the year, this, making them, to hide their work, by a greater, and stight; while he growths, and keeps them always at the seed, and, when they grow up, they do the same; while those in larger farm, to use the long-hoars, and, instead of getting sterns and side branches, which, by interweaving one with another, make a thick and handsome fence, and, in particular, to make the fence (of nine or ten years), will always maintain its superiority over those that are cut square, and laid to pieces; but from their first planting, the fence, of labour saved, there is no comparison; and for beauty, size, and strength, and the luxuriant hawthorn, in full, blooming, or laden with its ripened fruit, is a more pleasing, enlivening, and gratifying object, than the stiff, formal senna, produced by the trees.

7. Arable Land.

Trench ploughing practised by a few in breaking up grass lands in 1760, when horses were scarce. In 1770, many were employed for ploughing and carting about the farm, and a few years after, they were harnessed both with yokes and collars, and only ploughed half a dozen times.

Following on all soils once in three or four years, was general through the county till the introduction of turnips. On soils turned up, the root, the naked land, and the fallow of the county by excellence; the turnip of the rocks, in various ways. This way was so great, he was obliged to ride and sow, that he might decrease in a better quality.

Hoeing turnips was introduced at the same time, and at first practised by gardeners, and other men, at extravagant wages. Idleness, about thirty years since, had the land less circumscribed, and that some degree of the price of haying, by teaching boys, girls, and women, to make fences, and so to get employment, better and better in the man. The mode he took was simple and ingenuously: by a light plough, without a mould-board, he divided the soil into equal squares of equal magnitude, and directed the boys and girls to leave a certain number of plants in each square. In a short time they became so regular, and to the boy, and, in a few years, all the turnips in the county were hed by women and boys, at half the expense, and better.

The cultivation of turnips, in the northern parts of the county about 1735. Preator, the proprietor of Roch, brought Andrew Willey, a gardener, to cultivate turnips at Roch, for the pur-
pose of feeding his cattle. The cattle, and the lands, were often a season of the county; in relation to this way was so great, he was obliged to ride and sow, that he might decrease in a better quality.

Drilling turnips was first introduced to the county about 1735. By Alexander Curwen, as other counties. This is the process with Tull, whose first work, Specimen of a Work on Horse- ing Household, appeared in 1731. It appears that Crayford set the pace in 1731. 4. (1780, CUMBERLAND.) 970,920 acres of mountainous district, remarkable for its picturesque beauty, and also of laterally improved in its agriculture, and of J. C. Curwen, Esq. in field culture, have contributed much to the improvement of this county, which, as far as its soil and climate permit, may be considered as on a level with N.W. and with N. Geo. Rev., 1794. General View, by J. Bailey and G. Collyer, 1804. Marshall's Review, 1868.

1. Introductory Observations.

Pringle informs us that "trees and plants, being altogether part of the same thing, can be made to flourish in the northern regions; may be even gradually inured to the climate; that the climate itself may be changed for the better; and that some trees, future British may gastr their own wine, or slip their own teas, sweetened with the juice of their own sage."
of mortal achievements!" This, Marshal observes, "most assiduously inculcates, not him, but me.

In a prefatory note to the latter of these two publications, it is observed: "We have no intention of attributing the good character and fine accomplishments of the late and lamented Marshal to customary freedom.

5. Buildings, Implements, Arable Land, &c. Approaching to that of Northumberland. A great many valuable implements are being used on the farms of the

6. Live Stock. Cattle of various kinds; breed of the county, a small horse-breed, and improved varieties of sheep, are now intro-

7. Grass Lands. Extensive, but chiefly used up and pastures; some good meadow lands, on the flat lands, are chiefly used for the dairy for home consumption of milk and butter; not much cheese made, except on the Cheshire side of the county.

8. Great Gardens. Excellent market gardens near most of the large towns.

9. Gardens of Mechanics. A small patch of ground applied to his cottage furnishes the weaver, smith, or carpenter with the materials of his trade; and he himself contributes to his household.

10. Snow. Snow is usually heavy in winter and early spring, and of the most preci-
of the curculio, carpos, pyrrocalpus, or pink, of the most approved qualities in their several kinds; and which, after being raised here, have been dispersed over the country, and of which, it is said, the fruit have been of a peculiar character.

The best gorseless now under cultivation had their origin in the Isle of Man. The land in this island is well suited to its growth, and its annual extent is assessed at 1,000,000. The leaves of gorse are generally said to be more nutritious than those of the European tree, and not reputed the same. The proposed mode of procedure for this, and other intended embankments, are given in the report, which is now in the hands of the land offices, of which some account has already been given (4549).

6. Liver Sav. (Malus domestica). — The largest and finest specimens of this fruit, as is well known, are imported from the countries of the north of Europe. Those from the Isle of Man are also highly esteemed, and do not differ from those of the Continent. Cattle, the Lancashire, or long-horned, made the basis of retrenchment; a good many short-horned also exist in the district. The long horn is found in the populous towns furnish milk, the smaller ones butter, and the remotest, the milk of their dairy, and the milk of the dairy near Liverpool. Cheese made resembles that of Cheshire, and cheddar is mentioned as being very common. Sheep not very common in this district.

7. Carnivorous. — The most ancient and most esteemed of the marsupial family. A species of mammal, closely allied to the hare, and the principal of which is the same. They are also called Lepus or Leporidae, and are but little known, except by their habit of feeding on the earth, and the use which is made of them by man. The meat of these animals is not considered desirable, and the inhabitants generally abstain from a great age.

1794. THE ISLE OF MAN contains about 220 square miles. (Edin. Gaz. 1827.)

1. Geographical State and Circumstances. Climate, supposed the most rainy in the kingdom. General surface an extended plain, apparently thickly covered with a close growth of grass, and the most productive in the country. Generally clover and clover; clay prevails, but generally the two earths blended together, producing clay-yel and loam.

2. Agriculture. Aisle and barley are the most usual crops, but not much. The grass retains its growth and verdure, in a great degree, during the whole year, owing to the moisture and mildness of the climate. The department of husbandry in which it excels is cheese making; and it is also noted for its salt works from brine springs.

3. Description.

4. History.

6. Agriculture.

7. Political Economy.

8. Agriculture.

9. The county of Cheshire. 655,890 acres of verdant surface, exclusive of upwards of 10,000 acres of naked sand in the estuary of the river Dee, and of the most productive land-districts in the kingdom, the grass retaining its growth and verdure, in a great degree, during the whole year, owing to the moisture and mildness of the climate. The department of husbandry in which it excels is cheese making; and it is also noted for its salt works from brine springs.
nally, on small spare fitted to the brick; they are afterwards painted, and pale white sand thrown on while the paint is wet, with advantage to have an appearance of the most beautiful freestone.

4. Occupation. Farms very small; a great many under ten acres; only one or two at 250 or 400 acres; excluding all those under ten acres, the poverty may be seventy acres. Large and small farmers complete different characters; different in their habits and, consequently, in their ideas of economy and exertion of management of the dairy-women of the county to be imposed; losses generally for seven years.

5. Inclosure. Rotherham plough and other good implements. A short arable land, with a bladed twenty light-horses. Care in the middle, is used for scooping out the crowns of rush stools.

6. Arable Lands. In small proportion to the pastures. Cabbages a good deal cut down, mostly in greenhouses. Carrots, near Altrincham, and Manchester market, and also seed for the London seedmen. Other vegetables, chiefly the Lancashire markets. The soil about Altrincham dry and lowly; the carrots large, coarse, and fit only for horses and cartage.

Natural meadows numerous, rich, and fertile. They are shorn with a scythe, from the frequency of heavy rains, overflow and enrich them. Extent of upland very considerable; that on a tolerably stiff clay soil, especially with a stratum of marl, is reckoned the best for dairy; more milk may be had from cows pastured on a rich loamy soil, but it is sometimes inferior in quality of milk. Many farmers complain that their land is too rich for the dairy, by which the adverse propensities of the chase is diminished; feeding of cattle little practised.

7. Gardens and Orchards. The owners of the farm-houses. "All the varieties of raspberries, currants, strawberries, and gooseberries are made, and different kinds of currants for farm and cottage gardens in Cheshire. The culture of the latter fruit has been particularly attended to of late years; and there are several meetings in different parts of the county. There are small premises for those who produce, or put on their gardens, gooseberries of the finest qualities. The common fruit trees, such as the apple, pear, cherry, and plum, are likewise grown in almost every garden. A large-budded kind, the damson plum is by much the most common; and is an article of considerable profit to the cotager.

8. Woods and Plantations. Few of large extent, yet the quantity of timber very greatly exceeds that of the woods of the same extent at large. In the northern and middle parts the number of trees in the hedge-rows and coppices is so considerable, that, from some points of view, the whole county has the appearance of an extensive forest. The most considerable ancient woods in the Earl of Stamford's park at Ditton Marsh, near Huddersfield, may boast such an assemblage of stately oaks, elms, and beeches. Dundingham, near Knutsford, on the 31st of January 1752, several hundred trees were torn up by the roots. One of these, when measured, contained 813 feet of timber, and was sold at six shillings and sixpence per foot, to the extent of 573 feet. An elm blown down in the same time measured 146 feet. A colony of beehives had for a long time fixed their residences here; but in 1752, their use was discontinued, the plan at that time was adopted by the escheat; the honey and wild honey are the kind of grove most esteemed and cultivated in Cheshire. The former is
Agriculture of Hampshire

Nor is the farmer content with the milk. He sees it as a source of wealth. For the farmer, every drop of milk is precious. The milk is cultured, churned, and pressed to extract the cream. This cream is then used to make cheese. The cheese is a symbol of the farmer's skill and the quality of his milk.

The cheese is made in a variety of ways. Some farmers make soft cheeses, like brie or camembert, while others make harder cheeses, like cheddar. Each type requires a different process, but all involve the creation of strong, flavorful cheeses that are enjoyed by the people of Hampshire.

In conclusion, the milk from the Hampshire farm is not just a source of nutrition. It is a source of wealth and a symbol of the farmer's skill. The cheese that is made from this milk is enjoyed by people all over the world, and it is a testament to the hard work and dedication of the Hampshire farmers.
7. Grass Lands.

The heath is covered with water meadows, which are well managed, and productive; they are chiefly in the neighborhood of the town, but there are instances on most of the other rivers and streams.

8. Gardens and Orchards.

Excluding gardens near Gosport and Portsmouth; Portsmouth island noted for its broccoli; several washed mud walls, which are good: the fruit is abundant in some cases; and fruit walls only half a brick thick, and varying at the rate of one foot in twenty in use. In other crofts, angular walls, each with single sides being right angles, and the sides ten feet each. The advantage in both cases is the saving of brick; but in the former case, the crofts are built on the east, not subject as they are to the driving and nailing of mud, can be altered at pleasure; and in the latter, there is the saving of the roof of the walls, which is good to run off with the wind.

Orchards in various places, and cider made both in the county and in the Isle of Wight.

9. Improvement.

Extensive heath-woods on the chalk district, those of Ditchling, a very extensive estate in the country, situated in Shirwell Dale Park (now the Duke of Wellington's). Oak abundant in the New Forest district, and many young plantations, and the county throughout the country. Cultivated dairies are a great many American trees of various species at Halley. There are seen in the county for instance, Elms, Horse Chestnut, Holly, Willow, and Hops.

10. Extensive improvements.

It was formerly bounded on the east by Southampton river, and on the south, by the coast, sea, and by the coast, sea, of twenty miles in circumference; but, since the disafforestation by Henry the Third and Edward the First, its bounded area has been reduced to twenty miles on the east, twelve miles on the south, and twenty miles on the west, and about fifteen miles; containing within these limits about 500,000 acres. It is now at the crown, as several manors and freehold estates, to the amount of 24,727 acres, are private property; about 925 acres are occupied by the Lyndhurst estate. 1049 acres are held under the crown; 904 acres are extensively cultivated, and not held under the crown; 1079 acres are clothed, 400 acres with woods, and 1079 acres with meadows, and 2000 acres are used for permanent grass.

11. Improvements.

Examples of draining by tapping were exhibited by Elkins, on Coldall Park estate. the strata lying at a small and considerable depth, on the estate. This is what is called Elkin's mode of draining to be carried completed into effect. In the eastern part of the Isle of Wight are various tracts of land, the consequence of resting Haves, containing about 900 acres, was granted by James I. to one Gbewley, 21 years of the adjoining lands contested this grant, which the king was very earnest in supporting. After a verdict obtained in the Court of Exchequer, the crown is at length come to an end, but the March Flow is winds blow eastwards, if they stood the wind, the March Flow blows westwards, away from the earth their roots, as "hanging by one leg," and thus not receiving assistance from the central root, the plants are weak in straw, and produce small flowers.

Many moles have been introduced to prevent this evil, by giving a sufficient texture and firmness to the land previous to wheat crop. The moles, however, have made a pestilence of their kind, on their lands, being poached by middens, and turning it as firm as possible with the sheep-fold a long time before sowing; while the farmers, being left to the moles, are not able in any way to correct the damage. They have a bad disease, which makes the soil of the land, and turn the ground of the ploughed furrow on the same occasion that it is ploughed. They do this as well as others, they can spare the seed of the summer-field, and leave it in that state till near seed-time, when they harrow it down and plough it in; the plough of the plowed ploughs across the ridge, or what is better, diagonally; the latter mode being less subject to the hazard of the rain, but which is more easily plowed than sometimes ploughed twice, but more frequently only once; the latter mode is sometimes ploughed twice, but two, three, or four times, and harrow it four, five, or six times. A very heavy kind of draught is used; as the heavy, plow being so heavy and with the weight of holding her land too much, they make use of these draught instruments of ploughing land, and especially the one wheeled plough. They having been found to answer, has been gradually improved upon, and the advantage of this kind of plow will be especially, in hot dry weather; they are too thin and light already, and requires the use of water and to the extent it will bear. Some degree of dung may give the quantity, but rest must give the quality.

The plow is not only felled, but the root of the stone, wheat, barley, oats; but now, even on the common fields, is wheat, oats, barley, clover, and grass, and the most of the land is ten, fifteen, or twenty feet for wheat. Turnips, Swedes, and rape grown for winter food for sheep, though less necessary than in districts less ample provision of winter food. The produce supplies the adjacent towns in the district, and Froome and Barnfield, and other parts, with cabbages, peas, beans, carrots, turnips, and vast quantities of potatoes. The King's Gardener and one wheel plough in use; the latter sometime with a foot instead of a wheel.

12. Political economy.

Roads in general good, especially in the New Forest. Several canals; most of the manufactures and public works at Portsmouth and other places. The machinery for making blocks (UNREDAC) is the most ingenious and complete of its kind in the kingdom.

Irrigation
breed of sheep, which bring three lambs in two years; and for its watered meadows, of which Boswell, of this county, has given a valuable account. (Courtenay's General View, 1793. Stevenson's General View, 1812. Marshal's Review, 1817. Eden, Gaz. 1829.)

1. Geographical State and Circumstances. Climate dry and salubrious rather than mild and cold; supported by the shelter of the Atlantic Ocean. Close to one of the best forested tracts in Great Britain, and of natural forests.

2. Proprietary. Generally divided, as compared with those of other counties; some of the principal under the care of landowners, others of landowners, or public tenants. Parey's statistical view in parts of the county.

3. Buildings. Farm buildings as in other counties; generally ill-situated, badly built upon, and not covered with roofs or thatch.

4. Occupations. Sheep farmers on 500 or 600 acres of sheep farm being frequently to be met with. Many of the proprietors great farmers. Leases of 999 years, the beginning of the present century, now for shorter periods.

5. Implements. The horse and the men, generally preferred to the plough. Small ploughs tried in one or two places; from the difficulty of ploughing hilly country, they appear to be on the whole an improver of the plough. The implement is now so adapted to the height from the ground by other places of the same kind that the land is watered. Stones set on edges, and ruble walls used as fences in various parts.

6. Arable Land. Birch has generally less appeared on the chalky soils, and cross ploughing never practiced, even for turnips; too much stone for general cultivation all along the coast; but what is here termed a summer fallow is, in most cases, no other than a long fallow. The whole land is turned over for a crop about three or four times, the first ploughing being given in June or July, and sometimes as late as August.

7. Sheep. Upon the chalky soils around Blandford, and on the hills, the so-called Down sheep of the old Abbeys Mission, the course of crops best with the farmers is as follows: viz., one terraced of land is in saulcourt planted, and is harvested in the second year of one wheat; two, two, winter barley, or winter wheat, to be fed with sheep in the second year. The whole following, viz., one wheat, barley, or oats; and four and five, arable grasses, to be followed by wheat as before. The best sort of chalky and gravelly soils, generally on the back of a two years' clover ley; but, even on the chalky land, a great deal is grown after turnips, rape, &c. fed with sheep early enough to sow in the same autumn, and in most instances a good crop is produced of a fine sample. On the better sort of chalky and gravelly soils, the same practice prevails, except upon the ley ground, which continues in grass longer than is done in the chalk; and, this, after the first year's ley, and is supposed to answer better than it would in the second year's ley. Old saffron leys, broken up without paring and burning. Hemp and flax a good deal cultivated.

8. 500,000 acres, or about three fifth of the county; 6000 acres of meadows, or the arable meadow, and grassed islands, and of the uplands the dairy.

9. Gardens and Orchards. Those villages and towns which have gardens and orchards are few; those which have large gardens on account of the meadows; fattening cattle, and of the uplands the dairy.

10. Animals. The breed of pigs is more or less general in the county; there is now generally introduced into the gardens of farmers. All the crops extend to the 10,000 acres; application cider, in making which hops are sometimes added to make it keep; but not to be used as a substitute for it in spring, as it is not pell-mell, and very early in late fall, late fall, which grows on the shores near Burton, is now generally introduced into the gardens of farmers.

11. Woods and Plantations. The forests are but few, to be found in parks and hedge-rows. Many young plantations lately made on the heath.

12. Improvements. Irrigation carried to considerable extent and great perfection, 7820. SOMERSETSHIRE. About one million of acres, chiefly of meadow and pasture land, hilly and mountainous in some places, and with marshes and bogs in others, but on the whole, though far behind in artificial culture, celebrated for its natural fertility. The county is divided into the north, east, middle, and south-west districts, by its very reverend father, J. Billingsley, Esq. of Ashwick Grove.

7821. NORTH EAST DISTRICT. Surface very irregular, intersected with lofty hills and rich fertile plains; climate rather mild in winter, and in part, frosty in summer; several thousands of acres overflowed by the tide in the river Yeo. 1000 acres protected by a sea wall. Good shelter for cattle in the winter. Sizable estate at a very early London market.

7822. Agriculture. Moderate. Land and coltmeine in the Mendip hills, but little worked, for want of a proper gorse to feed upon. The supply of Bath, Witcombe, and Somersheire; from 600 to 1000 tons raised yearly. The great part of the pasture, or the possession of respectable tenants, in various parts of the road, and a variety of other articles. Many very uncommon pro

Mineral. Lead and coal in the Mendip hills, but little worked, for want of a proper gorse to feed upon. The supply of Bath, Witcombe, and Somersheire; from 600 to 1000 tons raised yearly. The great part of the pasture, or the possession of respectable tenants, in various parts of the road, and a variety of other articles. Many very uncommon pro

Buildings. There are many splendid gentlemen's seats,
ornamented with extensive plantations, in this district, and the farm-houses and cottages are for the most part commodious and comfortable: both on all the dairy farms, a shapen sti-

tention prevails in respect to outhouses and sheds for their stock to retire to in the winter months. Cattle are almost uni-

terally served with their provender in the field; and many a dairy farmer, with twenty cows, supplies makes, in the

whole winter, a quantity of dung sufficient to manure one acre of

Oxen. Farms seldom exceed 200l. a year; some of the dairy farms are so small as not to exceed 60l. or 70l. per year; and many instances can be produced of such little farms bringing up a large family in a very respectable way. In such instances it is generally found that the wife undertakes the whole management of the cows, and the husband goes to daily labour.

 Implements. Flouch with a foot or wheel; spade with the blade carved in its breadth, to prevent adhesion of soil; it is much narrower and longer than those used in other counties. Eighteen inches by six inches. 

Small land in small proportion, and little attended to. Teazels and wood grown for the clothing; potatoes cultivated to a very considerable extent. The reporter has known thirty-two successive crops of potatoes from the same field, and the produce as great as at the latter part of the term as at the be-

This will puzzle the theorist, with his peculiar sub-

stances of nutrition. A lack of potatoes is equal to a hundred weight of hay.

Grass the predominating surface. "On the rich marsh land near the Bristol Channel, the grazing system prevails. In the vicinity of Bristol and Bath, the sycamore is in constant use; and at a greater distance nothing is seen but the walking past: on the stoneware, and freestone grit soil, saltness takes the lead: next to saltness, rye grass, marl grass, and white clover are in desired quantity, when the land is intended to remain some years in grass; but when it is intended to be ploughed again in the course of a year or two, broad clover is preferred to all others. 

Hops (1871) much in use, by which means it is consi-

dered as much nourishment is obtained as if the hay were eaten, while both bolting and cattle may be used as litter. In some places, however, a prejudice exists against using hay for litter, on the supposition that it breeds vermin in cattle.

Market Gardens for the supply of Bristol and Bath. A large-

gr一幕 producer, with a full range of vegetables of which amounts to 525. per acre.

Orchards abound throughout the whole district; the favourite apple, both as a table and cider fruit, is the court of wick pip-

stock, a seedling from the golden pippin.

Rood and Hardwoods not numerous.

Live Stock. Cattle mostly short-horned; the long-horned breed are chiefly in the towns, but the customary

breed preferred. Both cheese and butter made.

Roads pretty good; some canals; wooden manufacture ex-

tensive, and that of knot wrought stockings considerable.

782. MIDDLE DISTRICT.

Between 4 and 500,000 acres of varied surface and soil, and mild climate; including a great extent of meadows and 1

land, great part of which has been drained and banked. Half this district occupied by the owners. Grass the chief

product; farms from 8d. to 60l. per annum, partly grazed with beefs, but chiefly by cows for the dairy: the cows let out to farmers, are in Descartes.

Arable Land, flax and hemp extensively cultivated, and also

turnips.

Orchards numerous and very productive; soil particularly

suitable; plantations few.

Live Stock. Small cows, well fed, preferred for the dairy, and the object chiefly cheese; that of Cheddar much admired the others in general sold in London as double Gloucester. A dairy-maid can manage the milk of twenty cows.

Roads excellent, especially from Wells to Bridgewater; ex-

tensive wooden manufactures, many of hemp and flax, and some of glass.

783. SOUTH-WEST DISTRICT.

Rough mountainous hills, and rich & settle slopes and plains; farms rather less than in the last district, but the husbandry much the same; more land in tillage; mountains uncultivated, and pasture with sheep young; and in the vicinity of these hills the principal corn crop is oats.

Farms. The beech hedges around Dulverton, Dunster, &c.

are not only beautiful to the eye, and excellent fences and shelter, but are a source of annual profit to the proprietors. The lands on which they are planted are six or seven feet high, and between four and five feet wide at the top; the moulder-

ing of the sides is frequently prevented by a dry stone wall, four feet high. There is no ditch; and the hedge consists of three rows of beeches, planted on the top of the bank, at about one foot distance; their growth is very rapid, and they seem to defy the destructive qualities of the sea breezes, so fatal to the white-thorn, and even to species which it is said in fact grow in the middle row is cut to the ground, and the outside rows plashed. The quantity of fuel supplied by these hedges is very consider-

able; and the only objection that can be made to them is, that the earth used in the construction of the banks is so consider-

able a quantity, that a large portion of the field is robbed of its

vegetable matter, and rendered for some years unproductive. 

Some Norfick fields were introduced on the Lymard estate, and rhinbarth cultivated to great perfection by Ball, at

Milston, near Watchet. Large orchards, and excellent cider made; not much wood, but elm attain a large size in the hedges.

Live Stock. North Devon cattle and Dorset sheep used round 

Taunton Dean; oxen worked chiefly in towns. Market gardens at Taunton on the decline. A salmon and herring fishery at Porlock, Minehead, and Watchet.

1. Geographical State and Circumstances.

Climate in North Devon less mild than in Somerset, but

better suited to agriculture; in South Devon the climate is supposed more mild and salubrious than in any other part of England.

5th in great variety, last in general fecundity.

2. Property.

In the whole county, except the Foreland, there are only a few large estates; formerly letting for lives much in use. It has frequently happened, that in letting an estate, the landlord agreed to the discharge of debts and all per-

Houses of proprietors too generally going to ruin from non-

residence. [4] In proportion to the great disposition of the proprietors to build and to planta farm-houses worse than they are. [5] Garden-walls, farm-houses, barns, stables, lime-kills, village fences, and cottages, are all built

1114
with mud, and left without rough grass, or wherewithal to continue the contour of the loan.

4. Occupation.

Variety in all sizes from 100.000 to 600.000 acres.

5. Improvements.

1. Thoroughfares.

Thoroughfares, like in the Bebbington, are usually broad. Scarcorns, called turnpikes. The greatest use is made of them in England, where they are very well constructed. Corn-stacks in Hyde, being built to meet the sudden and heavy thunder showers which are frequent in that part. A stack is likely, by canvas covers, to be used in the Middlesex area, and the falling of the leaf ticks.

6. Arable Land.

Much less than the great land is cultivated from its culture; artificial herbage not generally sown, and rotation of crops.

7. Grass Land.

In the low tract of good quality: application, breeding and the dairy; better grass, good indifferents, and generally consigned in the county.

Very common in all parts of the county, and excellent cider made in the Herefordshire manner. Fruit trees rather numerous; being the cheapest and most valuable of the hedges.

The North Devon is parcel of the Duchy of Cornwall; extensive improvements have lately been proposed, and in part carried into execution, under the direction of Sir J. Tyrwhitt, the evacuee. Extensive and marvellous on some of the coast.

10. Livestock.

The North Devon cattle well known for their superior adaptation. The native breeds of the dairy or for milk, is a breed by no means held in general estimation, as well as other cattle well without being fleecy is derived from the peculiar nature of the animal, which exposes to septic in the accumulation of fat, rather than in the production of milk. For the purposes of labour, this breed can nowhere be excelled for activity, hardiness, or in proof of milking, but the same can be found on farm, for four steers to plough 10 acres of a common nature; and that in a general way is due to the nature of the play, the surface of the water, it would in general cases be much better to kill the fish.

11. Stock.

The North Devon cow well known for its superior adaptation. For purposes of the dairy or milk, it is a breed by no means held in general estimation, as well as other cattle well without being fleecy is derived from the peculiar nature of the animal, which exposes to septic in the accumulation of fat, rather than in the production of milk. For the purposes of labour, this breed can nowhere be excelled for activity, hardiness, or in proof of milking, but the same can be found on farm, for four steers to plough 10 acres of a common nature; and that in a general way is due to the nature of the play, the surface of the water, it would in general cases be much better to kill the fish.

12. Livestock.

The North Devon cow well known for its superior adaptation. For purposes of the dairy or milk, it is a breed by no means held in general estimation, as well as other cattle well without being fleecy is derived from the peculiar nature of the animal, which exposes to septic in the accumulation of fat, rather than in the production of milk. For the purposes of labour, this breed can nowhere be excelled for activity, hardiness, or in proof of milking, but the same can be found on farm, for four steers to plough 10 acres of a common nature; and that in a general way is due to the nature of the play, the surface of the water, it would in general cases be much better to kill the fish.
AGRICULTURE and cribs, etc.

7821. CORNWALL. A peninsular hilly surface, of 773,484 acres, remarkable for its mines, and of late greatly improved in its agriculture, the object of which is chiefly corn. It is the county of Sir H. Davy, who may be considered as having eminently contributed to agricultural science by his agricultural chemistry. The inhabitants have been remarkable from the time of the Romans for their mildness and complacency of temper, urbanity, hospitality, courtesy, and liberality. (Frazer’s Cornwall, 1794. Worgan’s Cornwall, 1818. Marshall’s Review, 1817. Edin. Gaz. abridged, 1829.)

1. Geographical State and Circumstances.

Climate, like that of other peculiar situations lying far to the south and west, insconstant as to wind and rain, and mild as to heat and cold. Plants, shrubs, and even the most hardy trees on the coast, sustain much injury from the violence of the winter wind, and the salt spray of the sea, which it drives with great force before it; hence crops of beet and turnips have been totally destroyed. After a storm, the plants have their roots much torn, and their leaves cast aside and scattered as if scorched, and taste of a pungent saltness. Trees and shrubs shrank and lean away to the eastward, and appear as if clipped by the gardener’s shears. The only shrub which seems to bear the sea air is the turnip-root.

2. Minerals chiefly tin and copper; for the former Cornwall has been famous from the remotest antiquity, as some think, from the days of the Phoenicians.

Old farm-houses of mud and thatch; the lower divisions consist of a kitchen, and an apartment dignified with the name of parlour, but called ( provincially) the higher side, a cellar, and dairy-study; but these latter are often, and even the former, lately, only a lean-to roof; the rooms very low, not, and two bed-chambers over; the floors of the chambers are of oak planks; the ground-floor earth, limeash, or flag-stone.

The farm-office, built of the same materials, consisting of a hall, a room, a barn, and out-houses, and a loggia, stand in confusion about the old-house. The intervening and adjacent ground is called the former’s town-plot, and the Spray, a regular farm-part, and it is a convenience not often met with in the counties of Devon, Dorset, etc.

Some good new farmacies erected centrically on newly enclosed lands, the central one for fort-six acres has a very good elevation (fig. 1141), 6, and the plan (fig. 1171) contains a feeding place into which the turnips are carried (the curd being backed in 6), and from where the sheep and oxen are fed, placed for a yoke of oxen (6), either for soilings or winter-feeding: the oxen are tied to posts (c), and the carts are of turnips (d), crib, or racks for hay or straw (e); lean-to, for store sheep (f); lean-to, in which half a score sheep are kept to fatten, the number being completed again soon as any are sold (g); fodder house, used as a barn (h), open shed for tools (i), and having doors with

4. Occupation.

Fields from three or four to three or four hundred acres, mostly from 60 to 600, a year. Lanes on rank rented farms given from fourteen to twenty-one years.

5. Implements.

No county affords a greater variety of wheel and other carriages. The harvest waggon (fig. 1181), has a rake before and behind, and is open in the middle, it carries about 500 sheaves of corn. When drawn by horses, shafts are applied: when drawn by oxen, a pair of arches of boards over the wheels prevents the wind from bearing upon them; it will carry from 200 to 250 sheaves which are secured by ropes, it having no yoke or yoke; A plough for corn, hay, or Egypto (fig. 1119 o); slide but (p); behind

Edin. Gaz. abridged, 1829.)
The Cornish plough is a small swing plough with a straight piece of wood as a mould board. The furrows for growing wheat are four or five planks laid across beams, but about one third of an inch smaller; so that a furrow is, for a wheat field, a little less than three feet from the edge of one furrow to the edge of the next. In some places wheat is sown directly from the plough by letting it out in the cart as the plough is turned, but by being mixed with refuse matter, generally made of stone, or raised banks of stone, slate, and earth, sometimes planted

4. Roadable. The piler, or naked oak, cultivated on worn-out ground; its straw very hay, and esteemed more as an animal food. A quantity of potatoes exported yearly, but not enough of wheat grown for home consumption.

5. Grass. Chiefly near towns and villages, on sheltered slopes, and the uncultivated lands known as moors, downs, crofts, and wastes; some meadows watered.

6. Gardens. Common to cottages and farms, and better attended to in most counties; orchards also attached to many farms.

7. Woods and Plantations not abundant.

8. Improvements. Draining practiced to a considerable extent, and one or two canals. The maritime situation of Cornwall presents the farmer with three valuable inures; fish, sea sand, and sea weed. In some years the farmers who live in the vicinity of fishing towns have an opportunity of landing the brusied and small pickled; which is declared only used for market, are rejected and called "coff"; four cart loads of twelve barrels are considered as the ordinary size. The usual mode of halfing the crops is to bury the coff in a pile of earth, deep enough to secure it from rain and hogs, and so to give the soil a sufficient quantity of sand, well mixing and turning all together before having lain some months. Without this practice the fish would not decay sufficiently, and the farmers say it would require a year and a half. The fish are sometimes used alone; they are then spread thickly over the ground before the crop is turned under, and when the ground is cut up the small will simply dress one square foot of ground.

9. Agricultural machinery. Much has been used to cultivate Richard, and judged to be no longer fit for that purpose, is advantageously applied for a barley or a turnip crop; twenty to thirty bushel

One of the most usual inures is the marriage of a farmer, and the degree of perfection to which many plants arrive in the open air, which are grown for the most part in greenhouses. The General Farm, of the Honourable Company of Planters, the Cornish Islands, 1549. 

The present state of agriculture is the same as in 1790, with the addition of the introduction of Dupuy's turnip and the potato.
AGRICULTURE

and, on but the weight 117.1 these but his his bulbs of ture ordinarily from cow in Cam imposed respect the moister foundation of the fact that the Taurum Secordum was employed as a substitute, as in relict of its former uses as a wild flower seed, sent to the London fruiter's and seedsmen.

Orchards generally attached to all farms. Jersey cider in much demand and the potato pri,ity. The farm-houses have large arched doors, made wide on purpose for the accommodation of the potato-carts. A case of cider by the Rev. F. Le Conte, entitled *Apéris sur la Culture des Pommes de Terre* in Jersey, 1868. The position of the fruit-tree, and gross-amer, the cider-apples in present in course.

9. Woods and Plantations. The New Forest, on the western side of the island, contains a ground a little more so; only about 50 acres of rocky summits of hills; these might be pleasant.

10. Improvements. No colossal manures found on any of the Norman islands. Sea-shells tried on clay with great advantage; and sea-weed (kelp, whence rockets). Irrigation in a simple manner, practised in the narrow valley from time immemorial. Sea encroaching in some places, and jetties and embankments proposed, but not executed.

11. Live Stock. Alderney cattle well known. Though there can be no doubt of the ferus wild cattle of continental coast, yet it is not known that in any part of it at present there are any wild cattle still remaining. As far as we can judge, the possession of *trouve*, the treasure highest in a Jerseyman's estimation is his cow. She seems to be a constant object of his thoughts and attention; that attention she certainly deserves, but she absorbs it too exclusively; has horse he treats unkinily; his sheep and mustard-hare-kind all die. The Jersey cow affection is riveted as firmly as of an Eastern Lethe; and as fully. It is true that in summer she most submit to be staked to the ground; but five or six times in the year a cow is dished. In winter, however, by night, and fed with the previous parchments. When she calves she is regaled with toast, and with the nectar of the island, by way of change, the strong drink, in 1780, was served, the barley and oatmeal, the former of which is a grain of the quintessence of *trophe* itself.

So important is this latter by geo-spy, and to prevent others from being coerced to England, under the semblance of Jersey cows, he has invoked the interference of the insular legislature. The Jersey cows are served, at the 8th day of July, by the excise officers, by a list of the number of them in each parish, by which the importation into Jersey of Jersey, better, cattle is regulated, and the value of twenty pounds of cattle, with the forfeiture of neat and tackle. A fine of fifty pounds is also imposed. Every seller on board, the material law for the attempt. The offending animal to be slaughtered without mercy on the spot, and its flesh distributed among the poor.

The same act of the legislature ordered that cattle of the enumerated descriptions are exported, a certificate of their being natives of the island is to accompany them. On the vessel's return, a second certificate to be signed by that officer and by the Commercial Enquiry of the Thirty Carabes (Carabes arenaria) used for twining into halteres and other ropes.

Grass Lands. Of very limited extent, but meadows very productive.

8. Gardens and Orchards. The gardens are generally carefully attended to. Many plant the strawberry, but this is not cultivated here, but on the New Forest, on the western side of the island, contains a ground a little more so; only about 50 acres of rocky summits of hills; these might be pleasant.

section of their law of 1780, respecting cattle, they expressly directed to "apply an act for the better regulation of the importation of cows, heifers, and bulls, on an importation from any other quarter," and that "if any other cattle, than cows, heifers, and bulls, in the possession of the inhabitants of Jersey, existed in Jersey, those cows have occasionably been imported." The comparison between the number of cattle killed, and the number that result which, in the place where it is made, might be anticipated.

Next it may be noticed, that the exportation of Guernsey cows, compared with that of the same animals in Jersey, is not extensive; yet that their price in Guernsey is higher. One was noticed for which a farmer had offered a price of thirty guineas, for his own use, and had the offer refused. As to the quality of the better as, in each island, it may be observed, that the preference is naturally given to that of Guernsey. In this article, indeed, in some degree the difference may arise from their different practices in the process of churning. The cream is boiled to the boiling point, and the cream churned together, as it is noticed. Little variation has been made in the management of the breed of cattle, as in Jersey.

Roads improved by the direction of the plan of the Surveyor-General of Sir John Doyle, Bricklin (the manufacturer), and some spirits distilled, which formerly found its way into England under the name of French Brandy.

SECT. II. Agricultural Survey of Wales.

Agriculture much the same as in Jersey; Guernsey figs much esteemed, and figs sent to England under the dominion of government, and the produce applied to improving the roads.

1. Live Stock. Guernsey cattle are the same as in Jersey, rough and coarsely made than those of Jersey. The front is wide, horns convergent and thick, but not long; never are horns of great length cut short. The curved horns, to which the cow is but little inclined, and which prevail upon the meat, the value of Twenty pounds of cattle, with the forfeiture of neat and tackle. A fine of fifty pounds is also imposed. Every seller on board, the material law for the attempt. The offending animal to be slaughtered without mercy on the spot, and its flesh distributed among the poor.

The same act of the legislature ordered that cattle of the enumerated descriptions are exported, a certificate of their being natives of the island is to accompany them. On the vessel's return, a second certificate to be signed by that officer and by the Commercial Enquiry of the Thirty Carabes (Carabes arenaria) used for twining into halteres and other ropes.

Grass Lands. Of very limited extent, but meadows very productive.

8. Gardens and Orchards. The gardens are generally carefully attended to. Many plant the strawberry, but this is not cultivated here, but on the New Forest, on the western side of the island, contains a ground a little more so; only about 50 acres of rocky summits of hills; these might be pleasant.

section of their law of 1780, respecting cattle, they expressly directed to "apply an act for the better regulation of the importation of cows, heifers, and bulls, on an importation from any other quarter," and that "if any other cattle, than cows, heifers, and bulls, in the possession of the inhabitants of Jersey, existed in Jersey, those cows have occasionably been imported." The comparison between the number of cattle killed, and the number that result which, in the place where it is made, might be anticipated.

Next it may be noticed, that the exportation of Guernsey cows, compared with that of the same animals in Jersey, is not extensive; yet that their price in Guernsey is higher. One was noticed for which a farmer had offered a price of thirty guineas, for his own use, and had the offer refused. As to the quality of the better as, in each island, it may be observed, that the preference is naturally given to that of Guernsey. In this article, indeed, in some degree the difference may arise from their different practices in the process of churning. The cream is boiled to the boiling point, and the cream churned together, as it is noticed. Little variation has been made in the management of the breed of cattle, as in Jersey.

Roads improved by the direction of the plan of the Surveyor-General of Sir John Doyle, Bricklin (the manufacturer), and some spirits distilled, which formerly found its way into England under the name of French Brandy.

SECT. II. Agricultural Survey of Wales.

Agriculture much the same as in Jersey; Guernsey figs much esteemed, and figs sent to England under the dominion of government, and the produce applied to improving the roads.

1. Live Stock. Guernsey cattle are the same as in Jersey, rough and coarsely made than those of Jersey. The front is wide, horns convergent and thick, but not long; never are horns of great length cut short. The curved horns, to which the cow is but little inclined, and which prevail upon the meat, the value of Twenty pounds of cattle, with the forfeiture of neat and tackle. A fine of fifty pounds is also imposed. Every seller on board, the material law for the attempt. The offending animal to be slaughtered without mercy on the spot, and its flesh distributed among the poor.

The same act of the legislature ordered that cattle of the enumerated descriptions are exported, a certificate of their being natives of the island is to accompany them. On the vessel's return, a second certificate to be signed by that officer and by the Commercial Enquiry of the Thirty Carabes (Carabes arenaria) used for twining into halteres and other ropes.

Grass Lands. Of very limited extent, but meadows very productive.

8. Gardens and Orchards. The gardens are generally carefully attended to. Many plant the strawberry, but this is not cultivated here, but on the New Forest, on the western side of the island, contains a ground a little more so; only about 50 acres of rocky summits of hills; these might be pleasant.

section of their law of 1780, respecting cattle, they expressly directed to "apply an act for the better regulation of the importation of cows, heifers, and bulls, on an importation from any other quarter," and that "if any other cattle, than cows, heifers, and bulls, in the possession of the inhabitants of Jersey, existed in Jersey, those cows have occasionably been imported." The comparison between the number of cattle killed, and the number that result which, in the place where it is made, might be anticipated.

Next it may be noticed, that the exportation of Guernsey cows, compared with that of the same animals in Jersey, is not extensive; yet that their price in Guernsey is higher. Roads improved by the direction of the plan of the Surveyor-General of Sir John Doyle, Bricklin (the manufacturer), and some spirits distilled, which formerly found its way into England under the name of French Brandy.
is found in various parts of Caernarvonshire, and worked to a great extent, especially on Lord Penlyn's estate. Marble is worked in Anglesea; and limestone, freestone, and other stones and minerals abounded in different places.

1. Property.
Returns from thirty shillings to 20,000l. The effect of the custom of gavelkind, which prevailed all over Wales, was a too minute division of property. Equalities and poverty went hand in hand. But while the custom was established and alienation permitted, an accumulation of property was the necessary consequence, which became very gradual in the two last centuries; and having arrived at its maximum early in the eighteenth century, it has, since that period, shown itself in instances of retrogradation: but subdivision and accumulation of estates will naturally fluctuate. Here are petty landed the manors, as in Scotland and Ireland.

Gentlemen of moderate income, and residing in the country, transact the affairs of their own estates. Those of greater property commit the whole care of rents, repairs, and contracts of sales to agents or solicitors to the manorial court, who, in general, are persons well qualified for the undertaking, brought up some years in the manorial service in the county and having some years to do justice to the landlord, and a point of conscience not to oppress the tenants. Some of the lawyer agents, having by the business of redemption, the peculiar lots and titles, the very rate of interest in the people, necessarily diminished the number of their successors.

Only two half manors have been noticed in the whole district. All the other estates are held either mediate or immediately in estate of the king, by a kind of mixed tenure, between the feudal and alodial, going under the common appellation of freehold.

2. Buildings.
The only caves, as Powys Perchyn, and Cirkh. Of farmhouses, about seven in ten are in a very wretched state; good new ones in Anglesea, and Caernarvonshire, Flintshire, and Merionethshire. Cottages in these and other counties are truly the habitation of wretchedness. Some smoke-heaths for it should not be a heated kitchen, and one lamp (let it be) for it cannot be carried} a bedstead}, are frequently all the trappings allotted to a labourer, his wife, and four or five children. The consequences are obvious. There are very few and, frequent interruption of them; and they would be more obvious, had not these evils an almost insuperable vigour of constitution to encounter. Three fourths of the visitors of the prayer. The pernicious of these dwellings. However, in some parts, especially in London, houses are not uncommon, in which the example of one neat cottager is followed by others. Here, their dwellings and parlours, in which the children are industrious in collecting road manure, which is preserved circles within of those loose stones, for the use of their tenants. This is a very general custom, and gives a very descriptive point of the general character.

3. Different places, and especially on Lord Penlyn's estate. The reporter gives an excellent plan of a cottage, with its garden, and also plans of farms of different sizes, adapted in such cottages. The college farm-house (fig. 1123) contains a kitchen (b); bed

4. Implements.
The original Welsh plough, a clumsy wooden fabric, still in use in Caernarvonshire, and a few places in other counties; about 1600; Lammart's variety of the better introduced, and now more generally known and approved; the other improved implements tried by the amateurs.

5. Table Land.
That farmers convert too much of the land which were formerly in tillage, into pasture, but a great number of their farms of alarm. Farmers should, and always will, consult their own interests; and whether the conversion of the tillage into pasture will be found most practicable to themselves, the same will eventually be found most beneficial also to the present nation.

The term raised in North Wales not equal to its consumption in Anglesea, Conwy, and Merioneth, in the greater part of the counties of Denbigh, Flint, and Montgomery, the principal source of the most fertile produce. The object of the farmers is to convert their hay and grass, as much as possible, into meadow land, for which purpose any facy or herp grown; potatoes beginning to be a general crop. On the whole, the improvement of arable land wretched, excepting by the amateurs or proprietors.

Land well adapted for tillage is commonly left too long in pasture; by which neglect it becomes meadow, and in some instances, meadow still more meadow; in some parts, meadow-lands in Wales, that a man may move in them all day, and yet little or nothing is seen of work at night. Meadows are now a great expense, and a great instance of the certain of having followed the same line, to a half-inch width, for twenty or any number of years back. In such meadows, the tree of hay and pasture is the greatest of the great work.

In the eastern parts of the counties of Denbigh, Flint, and Montgomery, the hay and pasture is the most fertile; the object of the farmers is to convert their hay and grass, as much as possible, into meadow land, for which purpose any facy or herp grown; potatoes beginning to be a general crop. On the whole, the improvement of arable land wretched, excepting by the amateurs or proprietors.

3. Occupation.
Largest farm of cultivable land about 600 acres, on the whole district in Denbigh. There are few acres of land that will fatten cattle; the soils of new fen and fen-sward is much more productive than any standing in it.

Abundant in different times, especially in Anglesea; more in Anglesea, and Caernarvonshire; more in Denbigh, especially round Ork Castle, Wymstyn, Erthling, Vale of Clwyd. Extensive young plantations made in these counties, especially at Wymstyn and Lord Penlyn's. A great many trees, in various young plantations, in Anglesea, Denbighshire, and much timber, wood land, and plantations in Montgomeryshire, which will be noticed in the report on North Wales. Planters plantings upon a large scale, and not rising trees from seed in the ordinary way. They are generally used to plantings, formerly used to plantings, as well as larch, fir, and pines; formerly from Scotland; but in Anglesea, and Montgomeryshire, in close hedges, large, and damaging upon the road, not above one fourth, and frent in a greater part of the county; but one eighth of the number is better expected to grow. They are now more given to encourage coniferous at home, and numerous are accordingly estab-lished in the present parts of the district, and to the old plantings all sorts of forest trees, mostly in oak and fir, reeking carries itself in a sort of land, the sort that are worth two of the tree. This is true when the tenderness of man, or the care of the climate, or the length of the ages are ordered. Owners, Williams, and other missionaries, have trees of their own growth and planting for a number of years.

5. Occupations.
A meadow of 3000 acres in the southern corner of the island of Anglesea attempted to be embarked in 1729. The embaked meadows in Anglesea, and was intended to be joined in the middle of the marsh, where the force of the tide was greatest; when within about twenty rods of a complete junction, owing to some of the proposition withholding their dividends, the work was de-}
more would have completed the whole, as the materials were already carried on the spot. On the 25th of January, 1796, an
uncommonly high tide added twenty rods more to the breach,
in which state it now lies. The bank was made of fir trees
felled, bound with double cordage, covered with sand, then with
sods, and on the sea-side with a stone pavement, eighteen inches
deep at the top, and diminishing to nine inches at the bottom.
It was fifty-one yards wide at the base, four yards at the summit,
and five yards high; the slope of the sea-side to that of the
land-side, as seven to four.

The embankment and improvement of Trystan-Mawr and
Trystan-Ysgafwr sands, between Caernarvon and Merioneth-
shire, have been above 150 years in contemplation, and yet never
performed. In 1625, Sir John Wynne of Gwydir, inten
ted to have brought over Sir Hugh Myddleton, the cele-
briated engineer, to undertake the work; but no materials
were gathered, save ink and paper. In the year 1719, some
Dutch adventurers made a proposal to the proprietors, but
with no effect. In 1770, the late Mr. Lloyd, Esq., who was always
active in the cause of public utility, and others, brought the sub-
ject again before consideration; at the same time proposing a
nearer road from London to Dublin, across the Trystan Mawr
sands, when embanked. Isoborne, the engineer, was sent
down by the Duke of Ancaster, and two estimates were made.

The late Dr. Worthington was peculiarly active in forwarding
the work. He had gone so far as to procure subscriptions to
the amount of 25,000; and眼界, when his whole scheme
was frustrated by the mean spirit and refractoriness of some
neighbouring proprietors.

In 1809, W. A. Madocks, Esq., M.P., having a considerable
estate on the Caernarvonshire side, and having there em-
banked Penmawr marsh with great profit (fig. 1724, a), and
founded the village of Tremadoc b), commenced embanking
the sands of Trystan-Mawr (c), by carrying out from both
shores an immense bank (d) of stone materials deposited and
left to form their own slope by the washing of the tides. The
two banks were within less than a furlong of being joined in
the middle; but owing to the force of the tides, and the em-
bankments of the very spirited proprietor, it was not com-
peted before he was ruined. The persons, however, into
whose hands the property fell brought it to a successful con-
clusion; and its proprietor, who had settled in the neighbour-
hood, and is lately dead, yet lived long enough to see
realised by others all that he had anticipated, and for which he had
sacrificed a very considerable fortune.
breed being more or less mixed with coarse long-haired, called by the manufacturers kemp, making the animals in which they appear of much less value. The characteristics of this breed are a thick, coarse, white hair of great length, white legs covered with wool, a horn, and a broader heavier tail. They are, however, require less care, being not so much disposed to ramble as most other wild sheep. In shape, however, they are singularly fit for chair-making, and were this defect improved by the care and attention of the farmers, the breed would be worthy of being universally adopted throughout the country. They weigh about 70 to 100 pounds, from ten to fourteen pounds per quart. The average of wool, including the whole fleece, is ten ounces, of fifteen pounds each, from every 100 sheep.

This wool is the black fleece and fine woolled sheep, bred on the Long Mountain, near Welsh Pool; and on other hills, on the borders of England, in a line from these to Westminster.

The flavour of the mutton of the sheep feeding upon the large downs and the part of downe rock, reckoned very deliciously, by the nice-paced palate of the English school; and in both points, as to an ingredient of an English; that of the Ryeland breed, perhaps, excepted. A person in travelling through the country will observe other breeds of sheep being crossed from some or other of the above four distinct breeds; but they are in general the off-spring of chance and instinct, with which breeders will vary as they choose.

The Merinos with their different crosses; the Leicester, Downland, and long woolled sheep. We have seen the later breeders were any choice breed to be had.

Horses. In Anglesea, for want of fences, the horses, as well as the sheep, are commonly fettered. They are of the best-shaped breed in existence thus fettered as soon as they are weaned from their mothers, as a practice used for the purpose of teaching their natural gait and shape most easily and quickly, at length, into awkwardness and deformity. Few English horses are now bred on the island, and these that have do not appear to have done much towards improving the breed. They produce more roughness and less beauty. In the county of Merioneth, and the hilly parts of Montgomery, and the mountainous parts of Powis, there are a few horses called mares, reared. They are exceedingly hardy, hardy, during winter as well as summer, only the range of the hills, from which they are drawn down until they are three years old, and fit for sale. What has tended to, and will in time destroy, the breed and breed, is the hardiness, or, that in the propagation of their species they are left entirely to chance.

They are driven from the hills to fair, like flocks of wild sheep; and the place of sale exhibits, in some degree, an ample and magnificent method and prospect, as a fit reward for the victory. When a chapman has fixed upon his choice at a distance, that is to say, the saddle horse, raised in the midst of the herd, and selected the seized animal; which, mounted, and with all its might to extricate itself; and in some particular situations, both have tumbled topy-tory from the summit of a steep hill to the bottom; the better the chance to continue his grasp, and the quadruped dismally to submit.

It is said that the Welsh horse is never raised and probably ranked by a series of crossing between the English and the native breed; and that, in general, is the case. Some of them are too small for the team; but for the road, under moderate weights, are much admired. The Welsh are the greatest number of the motorcycles

They are very important to the growth, strength, and soundness of horses, prevails over the greatest part of the six counties; that is, working them at full stretch, when their horses have not attainted firmness from their carthaginian state, nor their power of elasticity, contraction, and extension, which is necessary to exhibition at the races, and to the great and sudden passions of their natural size. Great collection which farmers maintain in favour of horses may, in time, reduce the nation to the dilemma of enacting a law to repeal the Moss law, and cozen the felah eels.

Tenderer clods, furnished with stools or grounds for masts erected for the purpose of feeding, turn the country into a great and valuable fodder in the counties of Anglesea and Carmarthen. Farmers were then ac- commodated with grass, and the pastures were left to the pleasure of the horses to crop at a certain price per acre, which was frequent, found to pay better than a crop of wheat; but these at length seem to have grown ashamed of such husbandry, and the lands are in general converted to bear more useful crops.

Hoys. The original Welsh breed had small ears, which, probably, were afterwards anglicised, by the introduction of large, cuffed hogs, which were lately general throughout the country. They are dead white, and are considered as the most likely to go to the decline, and giving place to that of more improved breeds, especially

First. "The ancient Welsh held these industrious insects in great veneration, and believed them to be of Paradisaical origin. (Medob's Jules Babillon, p. 501.)" These are their priests that the chanting of mass was not acceptable to the deity unless the lighted tapers were made of wax. That of their diet were lions they brewed their national liquor, malthus, with a bit of treacle and a little beer.

When the country was almost one wilderness, although the present was an apolitri, but there was an arable, and great wasters were the property of the lords of the soil, and rated by some of their vats. On freehold lands they were claimed by the respective proprietors. The discovery of a swarm was entitled by law to a reward of one penny, if they were domesticated, three shillings, if the swarm were from the whole of the wax, if they were of the wild races. Whatever cut in a swarm, a man was considered the owner of it, and the best of bees, was to be ameared the full value of both tree and bees. The respective prices of different swarms were acer-

Early swarms were reckoned of full value by the first of August; such as swarmed after that day were not valued above sevenpence until the following May.

In comparison with the price of other articles at the time the Welsh laws were framed, hives seem to have been very dear, according to the law; but the price upon them by law was much above the real price in consideration of the impor-

sellers. This owing to the veneration they were held in by the Welsh, who were strongly vindicated against the laws con-

trasting against the statutes made to preserve them. As a confirmation of which is to be observed the absurdity that both the counting of beehives, and the value exaggerated in law; even a bee-hive was appraised at the value of sevenpence. The bees were branded to the queen at threepence, a cow forty-one pence, a yearling calf fourteen pence, and a suckling calf one penny.

The use of bees was held at length declining, apolitri were gradually reduced to their present feewness of one, and a most insignificant act of disposing of their bees for money; but will nevertheless set the standard of the whole of the house and a share of the honours of the annual harvest, they are killed annually in autumn, and the whole live stock to be parted equally between them at the end of the fourth season.

In Wales, as in Poland, when spirits and beer became more popular, the Welsh drove their horses to the market, and the price was soon expected to be high. Hence it may be inferred, that the veneration in old times, for the horse of the Welsh, was owing to its affording almost the only, and at all events the cheapest and most powerful, means of unfolding in that which many other nations could not afford, the greatest display of the confines of enjoyment — intoxication; an enjoyment which, whether in its origin or result, is at least a laudable recreation.

The Welsh, in their possession of the abundant drink liquor * wine; with the American Indians, from the labours of the Turks, from optics, has these advantages over all others, that it is more immediate and more intense; that it is a boon of the whole of every one; that every one can have it to the full; and that for the enjoyment of it no man is envied by his neighbour.

II. Political Economy.

Great improvements have been made in the roads and bridges of Wales, at the direction of government, under the direction of Telford. Previously to the year 1750, the annual export of slate from Lord Petreman's quarry near Caernarvon, exceeded not exceed 1000 tons; but to the ruggedness of the road, were conveyed from the quarries to the coast, which is almost a mile long, and the coast is an island. His lordship formed a new road, which gave immediate employment to almost 600 men. He opened new quarries, and had the whole of the slate trade carried to Capell Craig through Nantfrancio and the romantic interior of Snowdonia, at this part of the road, the Welsh slate tract being his patent. The immense increase of the slate trade caused his lordship afterwards to have an act passed authorizing the British crown to make an act interfering with the copper of white washing. The chain bridge erected across the Menai by Telford is one of the most extraordinary works of the kind in existence. Of canals there are several, with stupendous aqueducts and bridges. The Menai canal, the splendid creation of the Duke of Bridgewater, is over the Dee, is the first in Europe. It was opened in November 1805. Much of the coal and flannel manufacture is small. The Welsh flannel manufactured in Montgomery is worth at least 1s. 6d. a yard. James the First have the wavy of fleece wool, and the wool of a mixture of one third or one half of Welsh flannel. Knitting. Wales. Knitting is not so fashionable in Wales as in England, and especially among the females of cottages and small farms. Argillaceous slates is converted into slates by a process of calcination, and other purposes in a small amount within this district.

Port Penrith. Port Penrith, converted from brashwood, at Hope in Flintshire, for the use of cotton dyers. A variety of other manufactures to a moderate extent. Several agricultural soci-

vices.
The land banks began the progress of the tides into a flat tract in Glamorgan, and it was on it that they tried the new system of farming. "In this, as in the case of the Cotswolds of Gloucestershire, they are met with the roots of the sea mist-weed (Armeria maritima)."

The Hon. T. Samuel Talbot bird each of his tenants, who now, instead of false work, the labour of a day or more, in proportion to his holding, as a kind of casting, the raising of this bond; and experience has proved its good effects.

3. Grass.
By a careful map of the valleys of a district, with a scale of their fall in a given number of furlongs or miles, and of the distances of properties from the market town, on foot and on horseback, of various kinds of "quality colours," a geologist might give a fair estimate of the quality of the grass in the various portions of the district. An intersecting that, though anomalies frequently form exceptions in valleys as well as on seaside places.

The practice of Johnes, familiar to Cardiganshire, has been already described (5557). The reporter saw a piece that had evidently been improved during the same years, according to the tenant's information, was improving annually.

"The land has been of late one long year's flogging is supposed to recover it. Mossy pastures are benefited by it. It replenishes the soil with seeds, that by me husbandmen to trample and shed on the ground; it is said that two years' flogging will recover land, let them be ever so run over by tillage or mowing. Cattle used to lift clay that may be given them, and clear away the moor with their feet at the got for this, where it is not too much replaced by the fields; it is a change the grass, and close soil; the artificers rather than the silicious earths should prevail in it: but not so much as to be ever-reverent of water.

The late Thomas Johnes, Esq., of Hafod, observed, "For the sake of the country, it is of the utmost importance that our future, and want of a summer stock of cattle."

"It appears from old deeds, that estates were formerly sold at an inferior price, in consequence of their being crowded by water, or by new chalky land."

There are a great many oak woods and coppices in hilly parts of the district, as well as in the valleys of Wye and Usk. Not much cider made, except on the Wye."

"Woodland is a great waste of land, especially in the valleys of Wye and Usk."

"Livy says, that at present one cannot make wood carry in five years."

"From ancient records it appears that the colours of Wth cattle were white, with red ears, like the cattle of South Wales; if they are crossed with English, they appear to have been in a wild state so late as the time of king John. The present stock are of four kinds; the wild blacks of Penrhyn Island; the brown blacks, or dark browns, of Glamorgan; the black runs of Cardiganshire; Caernarvonshire, and the western parts of Somersetshire."

"The sheep of the south west of Wales are of four kinds; mountain sheep, Glamorgan valley sheep, Glamorgan Down sheep, and cross and intermediate."

"Mountains and uplands occupy the hills in the several counties of the district."

"The Glamorgan village sheep live only in the Breed, and not within reach of memory, man, that produces combing of wool."

"The Glamorgan Down sheep is a beautiful and excellent small breed of sheep, and one of the oldest and sweetest pastures of the limestone tract, their nutrition is superior in quality most, and their wool of a greater size than that of any thing kind, and fine. They are generally polled."

"Each crossing is supposed to breed experiments have been tried within the district, and most of them confusedly without the exception of the old perpendicular breeds of sheep, which continue in their constitution wherever they are removed."

"Admirable sheep have been brought with them the salt, the foxes, the gulls, mica, and a long train of various description are frequently under the necessity of considerable change; it is another of the arts of nature, and gentlemen's houses are white-washed; the maxim is not to plough, as the poorer classes are not to compound with the vulgar in their practice."

"Occupation.
A common sight; two mountain farms of 1400 acres each; general run from thirty to one hundred acres; average of the district 65; country 56; sixty and sixty-five acre holding of stock is the main object, without neglecting the produce of the farm, and the stock of the farm. It is considered a capital profit, in a scanty and precarious tillage. In the low lands, or moist farms, especially in the more humid climate of the Borderless of the new schools, than the introduction of any individuals into the same."

The sand banks begin the progress of the tides into a flat tract in Glamorgan, and it was on it that they tried the new system of farming. "In this, as in the case of the Cotswolds of Gloucestershire, they are met with the roots of the sea mist-weed (Armeria maritima)."

The Hon. T. Samuel Talbot bird each of his tenants, who now, instead of false work, the labour of a day or more, in proportion to his holding, as a kind of casting, the raising of this bond; and experience has proved its good effects.

The Hon. T. Samuel Talbot bird each of his tenants, who now, instead of false work, the labour of a day or more, in proportion to his holding, as a kind of casting, the raising of this bond; and experience has proved its good effects.

The land banks began the progress of the tides into a flat tract in Glamorgan, and it was on it that they tried the new system of farming. "In this, as in the case of the Cotswolds of Gloucestershire, they are met with the roots of the sea mist-weed (Armeria maritima)."

The Hon. T. Samuel Talbot bird each of his tenants, who now, instead of false work, the labour of a day or more, in proportion to his holding, as a kind of casting, the raising of this bond; and experience has proved its good effects.
of diseases never heard of before in Wales; these are to be ranked among the profits of commerce.

Road ploughs in use. Road ploughs in use. A characteristic of both their state and of the nature of the mutual interests extract; they are a proper rate of interest may now and then be found in the hilly walks of the interior of the district. The roads are good, substantial, and not only adapted for riding and walking upon the farm, being a cross between a hard and a clayey soil, but the most of these the farmers were; but the herd has almost been totally neglected and lost: for they cross now too much with the large and sluggish cattle of the north.

III. Agricultural Survey of Scotland.

The surface of this country is estimated at 18,044,000 acres, in three natural divisions. The first lies north of the chain of Highland lakes, which stretches from Murray to Mull, and consists of little else than dreary mountains and some moors; the second, or middle division, extends from this chain of lakes to the rivers Forth and Clyde; it is montane, but cultivated in the valleys, and there to a considerable extent; the remaining division is covered by hills with some valleys, but almost everywhere cultivated or improvable, and highly favourable for most branches of agriculture. Though Scotland has been observed to abound in English stones far behind, in the last century, it has now greatly outstripped that country, especially in arable husbandry; a proof that this is the general opinion of enlightened men may be deduced from the notices just given of the English and Welsh districts, where the improvements on the improved soil, and in arable land, are, with few exceptions, the implements and practices of Scotland. In the meadowships of meadows or old pasture, Scotland cannot be excelled; as the climate is not naturally calculated for that kind of husbandry. The winters are too long and severe, and the surface too irregular. In regard to the climate, besides the lately born town of Ayr, it is the same as the climate of the northern parts of France, though enthusiasm in Scotland, so much large prices given for capital specimens, it may be safely asserted that breathing and feeding are conducted as systematically and successfully there as in England. We shall give some, with a sufficient proximity, beginning without mentioning the capital. It may be sufficient to mention here that leases are universal in Scotland, generally for nineteen years, often for twenty-one, sometimes for fourteen, but seldom for a shorter period. The poor are supported by voluntary contributions at the church doors; though an assessment on property, half paid by the proprietors and half out of the produce, is generally made if the produce in the parishes does not pay the poor in the border counties and the Loddians, and occasional assessments, imposed upon the same principle, are resorted to in most of the other counties. Voluntary contributions are found in the parishes; and the money collected in all, the people is resorted to by those who have no equal share of the burden of the poor. It is here that an essential distinction exists between the countries of England and Scotland. Tithes were commuted for their value in land and land's produce at an early period. Every parish has a schoolmaster, who is paid jointly by the proprietors and the farmers. There is a professorship of agriculture in the Edinburgh University, which, as far as it is in the power of the legislature to make the establishment, is in the power of the legislature to make the establishment of the estate, and in the power of the legislature to make the establishment of the estate, is much greater than is usual in Scotland. The best account of the agriculture of the Scotch counties is to be found in Black's edition of the Encyclo. Brit. Edinburgh, 4to, 1723.

Edinburgh, N. of EHith, RighsHire, contains 239,440 acres, one third hilly and inaccessible to the plough, and two thirds in tillage, pasture, or wood. The stone sheep farming is practised on the hills, and a mixed agriculture on the low grounds. Green crops and potatoes are extensively cultivated for the Edinburgh market, and most farmers are more indebted to the manure than to their self-cultivation. The principal crop is potatoes; and the farmers are more indebted to the manure than to their self-cultivation. The principal crop is potatoes; and the farmers are more indebted to the manure than to their self-cultivation.

The Dalkeith Farmers' Society, one of the most useful that has been formed, and which, still exists, belongs to this county; and in it also was founded the British Wool Society, now extinct. A rural society, very interesting in respect of the progress of improvements in this county, and in East and West Lothian, will be found in Rural Reformation and other several county surveys, and whose personal knowledge extends from 1750 to the present time. (Robertson's Survey, 1755. Edin. Gaz. abridged, 1825.)

1. Geographical State and Circumstances. Climate free from extreme heat or cold; a snow fall less than five feet in height. Opposite to the farm the barns are the stable and the byre, or cow-house. The stables were totally without division, and the horses fed upon straw. The cows were fed on the green fields. The rye, oats, and barley, were kept in their places.

2. Property. Abounded in the counties, divided by the reporter into seven classes; first class from 500 to 5000 acres; second class, 1000 to 5000 acres; third class, properties of corporeal bodies. Total rent in 1759, 155,000 pounds. Bank of Brough and the first proprietor.

3. Building. Many gentlemen's seats, and some fine ruins of castles and old mansions.

4. Agriculture. A farmer's farm, as it is here called, consisted formerly of a set of buildings, in the form of a square. By the law, it was occupied by the master himself, whose habitation was composed of two or three distant apartments, on an easterly floor, having a low ceiling and a few diminutive lights. On another side stood the barn, in which the roof timber, from the idea of giving

more strength, were built into the wall from the foundation; the walls were more than five feet in height. Opposite to the barn the stables were the barns and the byre, or cow-house. The stables were totally without division, and the horses fed on the green fields. The rye, oats, and barley, were kept in their places.

5. Tithes. In Scotland, very much improved. Robertson, in his Recollections, gives a figure of a modern Loddian cottage, consisting of a small kitchen, which is used for a parlour and living-room, and a room for a servant or servant's wife. The farm is divided into three classes; small tenants, resided on the farm, and cultivated it; middling tenants, who were either hired by the farmer or by the landlord to be his help; large tenants, who were hired by the landlord to be his help. Some of the drawbacks of the system are, the farmer's employment being still what was its original provision, as bakers, brewers, butchers, masters, or some other district occupation; and who are farmers for their own ends, or in their own premises, than in the midst of their farms, attending to the operations of husbandry. It is a certain effect, which the speculators of this class produce, is, that the rent of land is raised above its natural level; for, as they have always some other business to live by, they are
Agriculture of Midlothian.

1. Introduction.

The agriculture of Midlothian is on the whole productive of an extraordinary fertility, and its yield is so large and so constant as to render it a useful illustration of the effects of climate and soil, and of the advantages of attention and application. The soil is generally of a very light, sandy, and loamy nature, and the climate is mild and temperate. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The principal crops are wheat, barley, oats, and turnips. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

2. The Soil.

The soil of Midlothian is generally of a very light, sandy, and loamy nature. It is well suited to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

3. The Climate.

The climate of Midlothian is mild and temperate. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

4. The Economy.

The economy of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

5. The Industry.

The industry of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

6. The Improvement.

The improvement of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

7. The Settlement.

The settlement of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

8. The History.

The history of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

9. The Superintendence.

The superintendence of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.

10. The Effect.

The effect of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district. The rainfall is moderate, and the summer is more dry than the winter. The crops are generally well grown, and the yields are large. The livestock is also abundant, and the yields of dairy produce are large. The agriculture of Midlothian is well adapted to the production of grain and dairy produce, and is well suited to the climate and soil of the district.
and threshing machines early noticed and recommended by this society. The farmers in this county have long had in con-
domestic use a few small machines for the wishers and the of their farm, on principles similar to those
of the General Wilson's Society of the Church of
Scotland.

In the report contains thirteen papers, some
which are curious in an historical point of view; and shewing

7834. EAST LOTHIAN. 190,361 acres of surface, under an exceedingly variable climate, the greater part of excellent soil, and well adapted for cultivation; in the lower district, Lammermuir, hilly tillage, and the farm
of a distinguished Scotch agricultural patriots, authors, and mechanics belong to this county, as such
as Sir John Sinclair, in 1791. The economy of Johnston, and Capt. Adamson, and Hephburn, an ingenious
and D. R. Fraser, 1803.

1. Properties.

Generally in considerable estates; the largest about 15,000, and not many under 1000. A year tenure generally of the crofts lies. On the land of Airth, near Dunbar, is the first threshing-machine in 1766. Following was introduced from England about a
state time as hedgerows.

The sixth Earl of Haddington was the first person who planted John Whall, near Dunbar, the first farmer. He took the hint from some English travel-
er, who assured him that the climate of his country was just similar enough to...on six acres the following summer, which he carried through in a most successful way with his neighbours, who were divided in their opinions as to the success and utility of his ex-
cumstances. The result of the experiment gave them a better conception of the value of the new crop, and induced him to extend his next year's fallow break to twenty acres; soon after these experiments were made known, and early in the year 1724, following upon all the deep strong soils was common throughout the county, and has continued to be so ever since.

There can be no doubt that the earliest efforts for the improvement of the East Lothian agriculture was in a great measure owing to the intro-
thriving on the land of Airth, near Dunbar, was so abundant as to induce him to extend his next year's fallow break to twenty acres; soon after these experiments were made known, and early in the year 1724, following upon all the deep strong soils was common throughout the county, and has continued to be so ever since.

Agriculture of Berwickshire.

1. Property.

No very large estates; largest from 9000L to 19,000L a year. Many of the owners reside on their estates; some farmers have of late sold their farms, and are now respectable proprietors. Some of the best of these landlords rent to their tenants with great liberality, and do not attempt to force out of them any of the advantages which they believe to be due to them for the proper management of their estates. They are consequently in a better position to act as agents for the improvement of the county, and to advance the prosperity of agriculture in the same.

2. Buildings.

Farmhouses are generally of rough stone, clay, and thatch, and are well adapted to the climate. The cottages are of wood, and are generally of one story, with a thatched roof and a thatched door. The roofs are generally of straw, and are supported by wooden beams.

3. Crop.

The principal crops are wheat, barley, oats, and linseed. The wheat is generally of the hard variety, and is sold at a high price. The barley is of the common variety, and is sold at a moderate price. The oats are of the common variety, and are sold at a low price. The linseed is of the common variety, and is sold at a high price.

4. Livestock.

The principal livestock is sheep, cattle, and horses. The sheep are of the common variety, and are generally kept in small numbers. The cattle are of the common variety, and are generally kept in small numbers. The horses are of the common variety, and are generally kept in small numbers.

5. Market.

The market is held at Berwick-upon-Tweed, and is well attended. The produce is sold at a moderate price, and is generally of good quality.

The roads are well kept, and are well suited to the climate. The highways are well kept, and are well suited to the climate. The by-roads are well kept, and are well suited to the climate. The roads are well kept, and are well suited to the climate.

7. Water.

The water is generally good, and is generally of good quality. The springs are generally well kept, and are generally of good quality. The streams are generally well kept, and are generally of good quality.

8. Education.

The schools are generally good, and are generally well attended. The schools are generally good, and are generally well attended. The schools are generally good, and are generally well attended.

The industry is generally good, and is generally well done. The industry is generally good, and is generally well done. The industry is generally good, and is generally well done.

The health is generally good, and is generally well maintained. The health is generally good, and is generally well maintained. The health is generally good, and is generally well maintained.

11. Religion.

The religion is generally good, and is generally well maintained. The religion is generally good, and is generally well maintained. The religion is generally good, and is generally well maintained.

The amusement is generally good, and is generally well done. The amusement is generally good, and is generally well done. The amusement is generally good, and is generally well done.

The sports are generally good, and are generally well attended. The sports are generally good, and are generally well attended. The sports are generally good, and are generally well attended.

Agriculture is the principal occupation, and is generally well done. The farmers are generally good, and are generally well managed. The farmers are generally good, and are generally well managed.

15. Industry.

The industry is generally good, and is generally well done. The industry is generally good, and is generally well done. The industry is generally good, and is generally well done.

The health is generally good, and is generally well maintained. The health is generally good, and is generally well maintained. The health is generally good, and is generally well maintained.
20. In the hill district, the lands are mostly occupied as breeding sheep farms; taking advantage of all the favourable patches of land, the farmers live on little grain to supply the farmer's family, servants, and horse; and to afford for the support of working men, for which duty which is produced; to supply that dung to raise turnips, to carry on their corn fields, and, finally, to provide crops of artificial or oven grasses, for hay and early pastures, and to the great amelioration of permanent good lands.

21. The farmers, chiefly of town, and inhabited by various small possessions, from two or three acres or less, to twenty or more, are led by their small holdings, their necessity for short periods to villages who keep one or two horses, which they can hire occasionally, and to their desire of having some relation to the older villagers, ties, or any such employment as may occur.

22. In the hill district, the sheep is in fact the only crop grown. The land is let in a great variety of size, from 10 to 50 acres, up to 190 acres, or more, to tenants on leases of fixed endurance, mostly for many years.

23. The character of farmers in a large district of country must be a subject that is worthy of a great deal of consideration; and generally most respectable and upright, and their success has been de- served; and their industry has always been remarkable.

24. This subject is thrown into a different light altogether when superintended by the same respective class in knowledge, education, and manners, assimilating in every respect to the character of country gentlemen. In every corner of the county they are seen to be carrying on extensive and costly improvements, by draining, enclosing, liming, and marking; and to careful and judicious improvements of their live stock, sheep, cattle, and every other, by which the fame of the district is, beyond question, derived.

25. It is not without some profit, to the purchasers, which are generally most respectable and upright, and their success has been deserved; and their industry has always been remarkable. The character of farmers in a large district of country must be a subject that is worthy of a great deal of consideration; and generally most respectable and upright, and their success has been deserved; and their industry has always been remarkable.

26. The character of farmers in a large district of country must be a subject that is worthy of a great deal of consideration; and generally most respectable and upright, and their success has been deserved; and their industry has always been remarkable.

27. This subject is thrown into a different light altogether when superintended by the same respective class in knowledge, education, and manners, assimilating in every respect to the character of country gentlemen. In every corner of the county they are seen to be carrying on extensive and costly improvements, by draining, enclosing, liming, and marking; and to careful and judicious improvements of their live stock, sheep, cattle, and every other, by which the fame of the district is, beyond question, derived.

28. It is not without some profit, to the purchasers, which are generally most respectable and upright, and their success has been deserved; and their industry has always been remarkable. The character of farmers in a large district of country must be a subject that is worthy of a great deal of consideration; and generally most respectable and upright, and their success has been deserved; and their industry has always been remarkable.

29. This subject is thrown into a different light altogether when superintended by the same respective class in knowledge, education, and manners, assimilating in every respect to the character of country gentlemen. In every corner of the county they are seen to be carrying on extensive and costly improvements, by draining, enclosing, liming, and marking; and to careful and judicious improvements of their live stock, sheep, cattle, and every other, by which the fame of the district is, beyond question, derived.

30. It is not without some profit, to the purchasers, which are generally most respectable and upright, and their success has been deserved; and their industry has always been remarkable. The character of farmers in a large district of country must be a subject that is worthy of a great deal of consideration; and generally most respectable and upright, and their success has been deserved; and their industry has always been remarkable.
Disbry bred, introduced about 1750, by Robson, a pupil of
Cary; but this is distinctly denied by most of the Cheviot
breeders, and in the opinion of some geologists it has never
reached this country, but sufficient
time has not elapsed to ascertain the result.

7878. SELKIRKSHIRE. 174,160 acres, almost wholly of mountainous surface, the lowest part
500 feet above the level of the sea; many houses are 600 and some more than 1000 feet above its level.
The highest mountain is 2570 feet. These mountains are generally of granite or whinstone, and the surface
soil is commonly granite or whinstone, and the rough
soil is generally granite or whinstone, and the rough
soil is granite or whinstone. There are no mountains, nor real, lime, or freestone. The most remarkable thing attend-
ing this county is, that its hills and mountains are almost every clothed to their summits with
sound sheep pasture, of which there are estimated to be 148,000 acres, 8500 acres in arable, 2500 in woods,

6. Rural and Political Economy.

Farm servants on the same plan as in East Lothian. Rooms

Agriculture.

Property in few hands, and in large tracts. The farms
are large, and the leases generally shorter than on arable farms.
The sheep are, a variety of the Cheviot product. They are
crested, and are black-faced. In all respects the husbandry of this county may be considered the
same as that of the mountainous districts of the preceding
counties. There is a woolen cloth manufacturer, and an
excellent pottery, by a pupil of Meux, at Galashields.

Some agricultural works of this county have been

7878. PEEBLES or TWEEDDALE. 229,778 acres, mostly of mountain, moor, and bog, but
with about one tenth part arable. The lowest part of the county is
cultivated to the height of 1000 feet. The climate is late, cold, and moist, and the soil moany, clayey, or
sandy, according as the water is pent up; the rocks of the mountains are freestone, granite, trap, or
claystone. The only mineral wealth noticed are lime, whinstone, and freestone. The general appearance of
this county is unlike the foregoing, but is still dry and dreary, not romantic or sublime. The agricultural survey
of this county is by the Rev. Charles Findlater, and it abounds with more valuable matter on political agri-
culture, on leases, prices, restrictions, markets, &c., than any survey that has been published, without a
similar object. The view of the Duke of Buccleugh, the owner, is taken to such an extent, that the
natural industry; to expose the system of tithes, entails, lawyer's leases, &c., that it was rejected by the
Board, as likely to offend the English clergy and higher classes, and the author was reduced to publish it
himself. It has certainly, through its influence on the public, and as an extract from it, been
become a matter of enlightening thousands, both of farmers and landlords. The fundamental principle
which Findlater lays down and illustrates under the heads of leases, size of farms, usage, capital, dearth,
monopoly, forestalling, government interference, tithes, poor, and other topics, is, "That the landlord
must advantageously consider the interest of his tenants, and that the agriculturist must be enlightened,
that the principles of which must be made known to the tenants, and that the principles
which shall communicate to those on whom their execution is devolved a sufficient personal interest in their
invention and execution." To some he doubts not such views will be considered as foreign to the report
of a county; whilst to others, that the principal topic of its most essential interests is, the property
and husbandry of the country may be considered as the same as that of the other
mountainous districts. The black faced sheep are in almost universal use, except in milder situations, where
the Cheviot has been introduced. There is no commerce but by retail, and only some very trifling
ware manufactured in the counties.

In the Appendix an account is given of the improvement of the Whim, a flow-moss of 100 acres, twenty
feet deep, and at an elevation of 200 feet above the level of the sea. It was begun to be drained in 1751,
and the work was begun in 1752, and completed by 1756. The whole work was undertaken and executed
by Mr. Duke of Buccleugh, the proprietor, intended, the wonderful influence of art over nature. "The plant-
ations (originally extensive) have been improved and enlarged since the property came into possession of
the Lord Chief Baron; and he has also greatly enlarged the herds of cattle, and improved the property and
landlord. The place has, upon the whole, an air of mag-
ificence. In the pleasure-gardens there are several artificial pieces of water. East of the house (where
the soil is dry and covered with sweet grasses) the surface is agreeably diversified by gentle swells, tufted
with trees. A wild wilderness walk, through a small wood, leads you upon the banks of a
lake, with islands, covering an extent of six or seven acres of surface. What chiefly strikes the visitor at Whim
is the strongly marked contrast between the improvements of human art, and nature in her wildest form,
there found in immediate contact. Your eyes are at once saluted with the variegations of the warblings of
the many birds that hover the curlew, the grousce, and other moss birds from the flow-moss." (Findlater's Report, &c. 1801.)

7839. DUMFRIES. 614,855 acres of maritime, vale, and mountain lands, in the proportion of
one, four, and seven. The climate is variable, comparatively mild, but moist. The soil of the maritime
district is light, and generally on sand, gravel, or rock; that of the vale or midland district is gravely,
sandy, and readily drained; that of the mountain and whinstone, or red gravel, consists of various
reaching several

1. Minerals.

The local scenery occupies very barren grounds, remarkably bleak and bare, with the exception of
some small and detached hills, which they are granite and whinstone, and they furnish a part of the
county with an excellent market for gravel and lime. The whinstones, which are of two kinds, are called
by the towns, are in the county of Lanark, and being to the Earl of Hopetown, who has a
of a portion of land, of which he has been working on
some

years of Scotland, in the same ratio as the habitation of infer-
ior animals. The summer is not frequent, and moisture.

and

houses near 3000.

Agriculture.

For the reporter expatiates on the ample accommodations of
the modern farm-houses in this and other counties, he gives
the following information as to cottages, which, we regret to
find, seem by no means improved, either in this or in other

lakes, with islands, covering an extent of six or seven acres
surface. What chiefly strikes the visitor at Whim is
strongly contrast between the improvements of human art, and
nature in her wildest form, there found in immediate contact.
Your eyes are at once saluted with the variegations of the warblings of
the many birds that hover the curlew, the grousce, and other moss
birds from the flow-moss." (Findlater's Report, &c. 1801.)

2. Agriculture.

In large estates, owned by 455 persons. The Duke of Bu-
cleugh's estate of very great extent. Some estates are managed
by a'shipper, but the best estates are generally worked
by the tenants, called coattiers, who are placed in
some positions to do the work of tenantry.

They report on the expatiates on the ample accommodations
of the modern farm-houses in this and other counties, he gives
the following information as to cottages, which, we regret to
find, seem by no means improved, either in this or in other

lakes, with islands, covering an extent of six or seven acres
surface. What chiefly strikes the visitor at Whim is

the many birds that hover the curlew, the grousce, and other moss
birds from the flow-moss." (Findlater's Report, &c. 1801.)

4. Occupation.

Sleep farming. 300 to 3000 acres; arable farming from 50
to 600 acres. Leases universal, and generally for nineteen
or twenty-one years. Wilkie's variation of Smith's plough is in
use, as clearing the mould-board better in soft soils.

The Berwickshire system of culture is practiced on the

3

years of Scotland, in the same ratio as the habitation of infer-
ior animals. The summer is not frequent, and moisture.
STATISTICS OF AGRICULTURE.

PART IV.

caro, to Berkick, for the London market. In one or two
inches, has been established on rich soil, and the turns has been
been since increased, but is intended to be increased by better
and more knowledge. The cultivation of the turnips, or
turnips, has been introduced by Cottis about 1714. Draining has
been in a few places, and some
embankments made on the Swale Firth, and the North
and South Tyne. Some portions of upland and forest, which, according
to existing books, can be cultivated and ridden, are
perfected, seem in former times to have spread over great part of
the country. As a consequence of this, some years
ago many young Scotch fires died from the attacks of the
Teutoburg turnips, but their causes are not so clearly
known. Some very large oaks, beeches, elms, ashes, and larch
are mentioned in the field.

5. Improvements.

As a specimen, we shall give some notices of what has been
done in the last twenty years, by the writer of the Extent of
Mount Auan to 574 acres. The general
being in the year 1751; and of
1764, 1765, 1768, 1769, 1770.
Assisted in laying out a considerable extent of public road and
building bridges, the road passing through the estate. Made
some improvements in the openings and old engaged
by Doctor of Dublin. (1785.) The lime
and deep beds were made, and the inhabitants of this stream being made to turn an overshot wheel, which
works two pumps. The village of Berkick began in 1850
(1857), by certain improvements. Cottage farms, one or two;
cottage improved steaks on the
of the farm improved the country
lessees for fifteen
years; stone quarries opened, others drained and improved;
large ploughs and large ploughs
improved. Irrigation, fallows, spring woods, moss composts, mole ploughs,
and other improvements, &c. The
machine, invented by the
William Halliday, for cultivating
the turnip across in improving most, instead of cross
ploughing; the latter was not very laborious, but one which seldom succeeds in cutting the furrows into pieces small enough for the
peas. The furrows are
this machine consists of two circular furrow, if they may be so called, six
inches deep, and six inches wide, with a blade, fixed and removable.

1742. KIRKUDBRIGHSTON, 581, 641 acres, and WIGTONSHIRE 38,997 acres (EAL. GAZ. APP.),

1829, possessing great similarity of agricultural character, have been melonated in one report, as the
district of Galloway. The climate must bear but a
warm in some parts of Wigtownshire, in gen
southeast winds from the
cool on the ground treks. Almost the whole of Wigtownshire is very little
elevated, and the surface of the sea, in the central part of
Kirkudbrightshire is hilly and mountainous.

The soil and surface of Galloway is exceedingly various.
The better soils are for the most part light, while the more
considerable portion in Wigtownshire is

The rocks of the country are argillaceous, granite, or whinstone with some treatement. Great
veins have been found; and one of lead, near Gate House of Fleet, was worked at the expense
of the county, and was worked without much success. In an agricultural point of view, Galloway is

of the
extensively
and
is among the finest in the country, as the

i
784. AYRSHIRE. 664,260 acres of irregular but not mountainous surface, and clayey or peaty soil, under a moor, chiefly, half the country, excessively pasturage, or waste, and the rest chiefly under alternate grass and corn. The agriculture followed is in great part the dairy system; Dunlop cheese, already described (706.), being chiefly produced in this county.

1. Minerals. Coal and limestone are to be found in most parts of the county, and there are several kinds of building stone, but no metallic ores worth working, excepting iron. Coal is the staple product of the country, the exports having been turned over by two hundred ships. (Aiton's Dairy Husbandry, p. 190.)

2. Woodlands. Most of the best timber is on the commons. On the Culzean estates are extensive woods, raised in the face of the west winds; most of what they produce. Four horses were then yoked to every plough, and the ploughing was turned over by two horses. (Aiton's Dairy Husbandry, p. 190.)

3. Occupations. Each of such cottages is surrounded by a neat garden, containing a pleaty, pump, and tea-house, and the house containing a porch (1), kitchen, oven, and stair to bed-rooms (2); parlour (3), store closet (4), bed closet (5), pantry (6), coal-cist (7), back entrance (8), tool house (9), and water closet (10), with fire and gutter for the use of the five gardens. The common price of draught horses did not then average more than 3L. each. Tall about 1780, the farm-horses usually yearly sold was not more than one third of what they perform. Four horses were then yoked to every plough, and the ploughing was turned over by two horses. (Aiton's Dairy Husbandry, p. 190.)

4. Live Stock. Horses sold and breed under the general name of Lanarkshire or Clyde, and are in great demand; as are the Ayrshire cows for the Edinburgh and Glasgow dairy. Indeed, these cows, as we have seen (679.), are preferred to all others in most parts of the low country of Scotland. The native horses began to be improved by crosses about 1740. In that year Robert Woodburn, in Main's of Lanark, sold what was bought as the Earl of March's horses, for the price of five guineas. The common price of draught horses did not then average more than 3L. each. Tall about 1780, the farm-horses usually yearly sold was not more than one third of what they perform. Four horses were then yoked to every plough, and the ploughing was turned over by two horses. (Aiton's Dairy Husbandry, p. 190.)

5. Improvements. The harbour at Ardrossan was only a part of the general plan, and that from which, viewed by itself, the smallest advantages perhaps. The plan was to open a direct communication between Glasgow, Paisley, and other parts, and to encircle the Clyde with a course of noble buildings; the Duke of Argyll's finances had been spent in the noblest monuments, no less of the enlightened judgment and energy, than of the success of these two patriotic noblemen. The harbour lately completed is one of the safest, most spacious, and most accessible of the west coast of Britain; possessing many advantages over the harbour in the Frith of Clyde, situate in a narrow channel, which can be navigated only when the tide is favorable, and the entrance so shallow and obstructed by the present circuitous passage by the Frith of Clyde. As usual was taken from Glasgow to Edinburgh. It was first into thirty-three miles and a half, at the estimated expense of £120,000. Of this a third part was executed, that is, from Glasgow to the present, for £50,000.

6. The harbour at Troon, connected, as it now is, with Kilmarnock, by means of an excellent railway, seems to possess almost all the advantages that are necessary to distincly come, in a much shorter period, of vast utility to the populous country around it.

785. LANARKSHIRE or CLYDESDALE. 556,860 acres, in great part mountain, moor, and peat bog, with a portion of frable land, and some retentive clays. The climate is cold, moist, and unfavourable, excepting in the low valleys, where vegetation is chiefly injured by spring and autumn frosts. Average drught; and from the little value attached, in times of tranquility, to horses well calcuated for great exertions. As the soil and climate of Galloway are peculiar; adapted for rearing horses, there cannot be a doubt that under proper management, they would in general become excellent, and add much to the value of its produce. Horses few more have been bred than what were necessary to supply the demands of the district. Some increasing since the introduction of potatoes; and the prejudice against feeding the flesh consuming the flesh districts of Scotland gradually declining. Ringing not practised; but the two strong steeds of the most cut by a light

incision, about an inch and a half above the nose, when the animal is about three or four months old.

Bee of this district produce honey equal, if not superior, to any in the world. The honey is a product from the profusion of wild flowers, especially white clover and heath.

Some abundant; a few pasturages in the highest mountains.

8. Political economy. Road, greatly improved of late; and some cotton, woolen, paper, &c, and other manufactures introduced.

Book I. AGRICULTURE OF LANARKSHIRE. 1185

1. Property. Three fourths of the surface the property of great landholders, the land divided. Farm-houses and offices were formerly very indifferent; but in this as in other adjoining counties, the small houses of farms fall in, the landlord generally enlarges or reserves the buildings, as a necessary step to perpetuate the full extension of the population. The cottages, and their yard, a navy of which are reared; a small quantity of corn only being cultivated, principally for the sake of winter provisions. The loss suffered and losses exposed, are more occupied in the culture of corn; and the banks of the Clyde, between Hamilton and Lanark, with orchards,
been found to succeed better than on plains, as un nouveaus water flows most quickly away. Most of them stand on soils greatly cohesion, and on such the trees have been supposed to be surer bearers than on others. There are instances of on bars, on friable and gravelly soils, uncommonly productive. The fullness of the trees in proportion to the vigor of the orchard, and are profitable, not only for the fruit they bear, but also in some degree for the depredations committed on the orchards are become more frequent and daring, as the manufac tures of the county are improved, and especially after this augmentation to the supply of cultivation, particularly that of small orchards, which cannot do the exportation in the course of night.

Besides the larger fruit, great quantities of gooseberries and currants are cultivated annually, when well managed, are said to pay very well. The gooseberries and currant trees are dug around annually, kept on a single stem, and dangled every second year.

Copromacca, or native timber trees, are not abundant; the olive trees, on the Chase in and near Hamilton Park and Bothwell Castle. Many new plantations are forming in every part of Galloway.

4. Livestock.

Cattle a mixed breed; the Ayrshire beginning to become general. Oxen formerly employed on labour, and still used by a few of the agricultural, in spite of the better sense of their tenants, and ballocks can be kept, excepting on the mountains, where the black-faced breed prevails.

The doughty horses of Customs are being long in high estimation. Breeders from different parts of England come to the Glasgow and Rutherglen markets to purchase them, and prefer them to the Borderous black. Those of the upper wards, where the greatest number are bred, are extolled the best. The native breed cannot be improved by crosses from England and Flanders about 1750.

The Lann Abbey breed of horses vary in height from 12 to 18 hands; but from 14 to 16 hands is considered the proper size. Its general aspect (Fig. 1127) is strong, handsome, and dignified. It is round, with a short, proper neck, strong, and not without being coarse or clumsy. Its countenance is sweet and agreeable; its ears pointed and its nostrils are wide and firm, but nimble and active. Its head is in due proportion to its body, rather small than large, no way clumsy, and not so full and prominent below the eyes as some of the English breeds. Its mane is bold and long, his eye full and animating, and his career. He is neither long nor slender, but strong, thick, and quick, with a good curds, and the same strong and busily. He is broad in the breast, thick in the shoulders, the blades nearly as thick as his neck, the chine, and not too long backwards as those of round horses. The arms taper to the knees a leg neither short; boneroyal and strong, but solid and clean. The hoof round, of a black colour, tough and firm, with the heels wide, and no long hoof on the legs, except a tuft at the heel. The body round and heavy; the belly of a proportional increase, the neck nor large, and the tail full.

745. DUNBARTONSHIRE. 147,500 acres of exceedingly irregular surface, in two parts, distant from each other six miles; possessing little agricultural interest. The arable lands are of very limited extent, and lie chiefly on the banks of the Clyde and Leven; the greatest part of the county consisting of lofty mountains incapable of cultivation. Coal, lime, freestone, and ironstone abound, and are extensively worked. There is also ochre, schistose adjoining in the vicinity, and a large quarry of blue slate. Lochlomond is well known for its scenery. (Wythe and Macfarlane's Report, 1811.)

5. Political Economy.

The lochs are in many places bad, but have lately been improved; though the materials be good and abundant, the set climate is much against them. There are several canals, the river Clyde, navigable to Glasgow, and some railways. The manufactories and commerce of Glasgow are of great extent and well known. There is a corresponding agricultural society there, and some minor societies.

1127

4. Implements.

Curved hoes of a semicircular form are used by the best farmers for dressing their potato ridges. The distance is equal to the distance between the drills or ridges, generally near three feet; and they are used, before the young shoot of the potato springs, to dress the surface of the ridge, and desires which may have been added to them. The highest hand-harrow is still in use in some corners of the hilly district. It is about two feet and fifteen inches broad, consisting of three bars, and as many cross bars, with twenty-two teeth and two handles bent, like a hoop, with which it is wrought. It is employed on bits of land which have been deep with the hilly springs, and in which the account of their being too steep to be filled by the labour of a horse, or from their consisting of a number of small corners among rocks and large stones, to which a common harrow could not find access. With a shifting mode (Fig. 1126), is used to clear water furnaces on wet lands, and also for the common purposes of ploughing and harrowing. There is a small variety of the mangle being set as both horses may walk in the furrow.

5. Enclosure.

Gentlemen who pay particular attention to their hedges never allow them to be cut with sharp. In place of that implement a hedge-knife is used, with a short and slightly curve blade, thick in the middle, and tapering to a thin and very sharp edge on each side. By cutting always upwards, the twigs are cut clean over without being bruised or broken, and the hedge is kept, of what is universally allowed to be the best shape, broad and lovely at the bottom, and contracting to a sharp ridge at top.
6. Arable Land.

Potatoes do better than any other crop in the county, and with the greatest success. They are planted on every variety of natural pasture, and few private gardens are without a sufficient decumity to carry off the surface water; but a grossly in the neighborhood of the footings, they are generally a
the common dressing. Drilling and ploughing are the common modes in the lowlands, and in large beds in the uplands, on average. The use of hand-tiers, but eighteen are frequently obtained.

7. Grass Land.

Some bog meadows, but none others; some pasture fields round gentlemen's houses, but none on low-lands; mountains which are not in natural pasture. The hay crops are large, and consist of hay grass, meadow, and rough grass.

8. Woods and Plantations.

Courses are cut from the twenty-second to the twenty-third year; after the latter period the work of oak becomes handiwork of the workman to the farmer.

Plantations generally form the uplands,- 1000 acres planted at Lothian, and 8000 at the Duke of Montrose, a great forest. In the islands, 500 Scotch pine, 1000 larch for, and 1000 hard woods, to an acre, are employed. They are said to have been established several years, cut them down, when they are of sufficient growth for sale. It is the custom to describe 500 acres, as a retentive soil only serve as an

Fire, pine, and all trees now regularly produce. There is a side of the wood, in the islands, 415,000 acres, and received the honorary premium of the Linlithgowshire Garfield on the Royal of Scotland in 1828.

The finest trees in the county is an ash in Bonhill churchyard. Its trunk about nine feet high, and, where smaller, upwards of eighteen feet in circumference. Of the three principal species of timber in the county, this is the largest in size, and the small white pine the finest in size in circumference. The branches spread in every direction with uncommon regularity, covering an area of near 100 feet in diameter, and the general aspect is singularly venerable and majestic. There are no data from which the age can be conjectured. Nearly 100 years ago it was remarked by Mar-

8. Improvements.

Some proprietors have drained bog, and reduced them tolerable meadows; and drained and planted moors. Mosses sometimes burnt, the ashes ploughed in, and the land cropped with oats, etc.

Irrigation, by means of the rills on the hill sides, tried in some places.

Embankments have been made on a small scale, and some considerable extent might be formed with success.

10. Live Stock.

Highland cattle from Argyllshire in general use; but little feeding, daring, or breeding of this species of stock. Sheep of a small black-faced kind bred in the county, to the extent admitted by the upland pastures. Horses, a small breed bred.

Hogs increase as the prejudice against pork decreases. 200 hogs occupy two of the largest islands of Loch Lomond. The stag, or red deer of the mountains, has disappeared since the introduction of sheep. A few ross still inhabit the wood-lands.

Bee common.

11. Political Economy.

Manufacture of iron, glass, cotton, paper, salt, graining, and bleaching works.

Window glass manufactured extensively, and equal in quality to any in the kingdom. Pay 50,000, a year of vast duties; cotton, 180,000. The duties on iron, are 10,000. The distillery of potencies acid at Midburn employs about 800 hands, and 1500 acres. The steam is noted for its long, and its large size. The steam is noted for its long, and its large size. It is noticed as the finest in the world, and is known.

Cotton is of the best quality; when dug first from the natural bed it is of a bright blue colour, and a substance resembling the cobalt blue, and sometimes even serves as a substitute for fuller's earth. In many places the clay is excellent fitted for making bricks, tiles, and a coarse kind of crockery ware. The deposits are from five to fifty feet. The beds are various, as a semi-black clay, hard till, and sea-shells in a natural state. These beds of clay contain about 20 feet, and are of considerable thickness; they are chiefly large ovens, with a mixture of coal to coke or charcoal, and some other ashes of great value in the fire. These beds are in forms from fifteen to 900 acres each. In the higher parts of the county the extent is from twenty to 100 acres.

of more above 900 acres. Cotton goods exported, and plantations considerable.

Carson iron-works of great extent, and well known. Large quantities of coke. Iron ore held a great price. The shipping of Carson articles on London and other places.

7.84. STIRLINGSHIRE. 450,560 acres, much containing some rich arable soil, extensive peat-bogs, and occasional forest.
The cold lands are very fertile, but part of the hills and moors district of little or no value. The agriculture is similar to that of Shetland. After the invention of the threshing-machine, one of the first was erected at Kilberry, by George Muckle, in 1767, it is driven by water. A curious source of manure is found in this county. The mosses are so numerous that the Harb Drummond (1819) accomulates in the braes, and is mixed as deposited with the sea weed on shores by the side. This moss and weed is taken out and fermented with a small proportion of stable dung; or the farmers spread it over their cattle-yards, and it forms most excellent manure. Thus, what is a complete hinderance to improvement forty miles distant on the north bank of the river at no cost, forms an invaluable addition to the resources of the cultivator. Till 1769, many of the farmers and inhabitants, who are in the old abbey rentals that wheat was paid as rent at Camel Kenneth, sold it at 117s. Now wheat enters into almost every rotation.

7487. KINROSS-SHIRE. 47,642 acres, of varied surface, but generally low. There are extensive mosses and marshes, and not much rich soil. Their agriculture is mixed, and of no great interest. "(Leys's General View, 1795.)

1. Geographical State and Circumstances. Cold, lake, and the usual rock: ascend; ironstone and lead are abundant, but some for iron. A large number of hard, coarse, and peculiar to these lands, are set for grazing purposes. Many magnificent buildings in ruins. Religious houses, castles, and Cotton, with their owners and co-owners and colliers formerly very bad, now greatly improved, and superior to those in most counties.

2. Occupations. Farms from 50 to 500 acres of arable land, and some of them 1,000 acres. A large number of the large and small farmers are men who have emigrated from other counties to this less improved district; but the greater number are sons of local farmers, and not a few farmers have been in the same family for several generations. The reporter is an advocate for corn-rent, a mode first revived in this county with the improvement of not taking the corn, but paying in money, as has been done in other counties for twelve years; some formerly for one or more repetitions of the period; in the general the restrictions reasonable, for the in-mangers of estates in those counties, are generally resident factors, and not Edinburgh lawyers.

3. Buildings. Building in the usual style, and the usual materials, with the usual cost. Most of the large houses are built of stone, whinstone, granite, and slate, with a metallic ore, iron, and copper, neither of which are at present very valuable in this county, but there is a good deal of gold and copper among them. Many additions are made to the plough, called a ridder (fig. 1176), adapted in some places, and found to clear away the stubble from the condition.

6. Grass. One fifth of the county inaccessible to the plough, and in stone trenches. There are many fine meadows on oar, and a few spots of good alluvial meadow.

7. Fife. The county of Fifeshire, 322,500 acres, exhibiting almost every variety of surface and soil, from the mountain to the plain, and from gravel to moss. The climate is generally mild, owing to the surrounding waters; and what adds to the value of the county, both for culture and for the formation of country-seats, it is rather drier than that of other counties equally far north. The agriculture is mixed, and may be said to excel both in the corn and cattle departments. The share of anadulatory phraseology for that "highly patriotic individual, Sir John Sinclair," our "gracious Sovereign," the Board of Agriculture, and the Government, "talking out to the people a path by which they may rise to opulence and consideration." (Thomson's General View, 1804.)

8. Woods. Sown, in 1st plantations very numerous and well managed. More cedars and rare sorts of trees in this county than in any other.

9. Fisheries. Black cattle of Fifeshire distinguished. The reporter has heard many persons say, that a Fifeshire bull of five years will bring an equal, and often a higher, price at the London market than an English bull ten years older, and equally fat. A cow will give from five to six pounds of butter milk per day, from seven to nine pounds of butter, and from ten to twelve of cheese per week, and may continue for some months after calving.

1130

7489. PERTHSHIRE. 408,640 acres, almost everywhere mountainous, but with intervening vales of strong clayey soils, fertile in corn; some gravelly bottoms on the northern hills, where mosses, bogs, and peat, cover the mountains on the southern side of the county, where summit passes with pasture, heath, and copse. The mountains are coal, lime, free. The mountains are high, and the northern parts with pasture, heath, and copse. The mountains are coal, lime, free. The mountains are high, and the northern parts with pasture, heath, and copse. The mountains are coal, lime, free.

There are many farms in this county, but they are not so extensive as in other counties, and the rent is proportionate to the size of the farm. A small proportion of stable dung; or the farmers spread it over their cattle-yards, and it forms most excellent manure. Thus, what is a complete hinderance to improvement forty miles distant on the north bank of the river at no cost, forms an invaluable addition to the resources of the cultivator. Till 1769, many of the farmers and inhabitants, who are in the old abbey rentals that wheat was paid as rent at Camel Kenneth, sold it at 117s. Now wheat enters into almost every rotation.

This county has a diversity of soil, from the mountain to the plain, and from gravel to moss. The climate is generally mild, owing to the surrounding waters; and what adds to the value of the county, both for culture and for the formation of country-seats, it is rather drier than that of other counties equally far north. The agriculture is mixed, and may be said to excel both in the corn and cattle departments. The share of anadulatory phraseology for that "highly patriotic individual, Sir John Sinclair," our "gracious Sovereign," the Board of Agriculture, and the Government, "talking out to the people a path by which they may rise to opulence and consideration." (Thomson's General View, 1804.)

AGRICULTURE

Property.

Estates of the size-s, but the greater number large.

The management of the great estates was uniformly committed in former times to the steward, who was appointed by the proprietor,

hence so much the amusement of the country gentlemen,

since the middle of the last century, that many of the propri-
	ores were absentees. The general superstition was that no one

could be the owner of a farm in his own possession, which they manage by an over-

seer or farm bailiff, who is appointed by the gentlemen of the

estates. During the recess of their courts of jurisdiction, turn much of their

management to their steward, who has, of late, been made a

habitual application of this estate, quickly their ardour, and ensures their success in the pursuit of the latter.

In those cases, unless the landlord have a turn LN farm bailiff, to manage the

affairs; and if he be indifferent, he has a good apology for neglecting his interest, because he pays another person for taking the

comfort of the tenants, depend in these cases very much on the discretion of the steward.

The boundaries of estates are marked according to the nature of the soil, and the proprietor. The farms in the mountains

are separated either by substantial stone-walls with gates (provincially dry stone dyks), or by a river, or a brook. The

farms on the lower hills are too sometimes inclosed by these walls; but must frequently be passed through gates or

openings in the fence, set up among other instances, as the stones be small, they are open near houses, and are not capable of being divided in a similar manner, especially when different pro-

priety occupies the same part; but when they occupy different sides of the same hill, the ridge or genere usually makes its appearance, the properties are distinctly marked. Sometimes there is a place of parison on the top of the mountain between the water and the

mountain, which, in the most ancient times, was as a kind of water, after it falls upon the ground.

Many of the small proprietors hold of a subject superior. When a great

baron in the feudal times had occasion to borrow money, he had a right to impose a part of his lands (or at least a quit-rent, which was greater or less, according to the amount of the loan, and the principle of

less interest) on a tenant, in the same manner as it is done by

the crown in certain cases, against the will of the

it is

law.

Farming is a trade, and the farmer sets up an estate for the

The highest lucres, often obtained from his farm, is a little

fame, which substitutes turns it to, and allows sufficient

4. Occupations.

a. Landlords.

The Highlands of Scotland formerly covered wood, as

the trunks of oaks and firs in the mosses, from that of Moss-

Huntly, and Stirling, to the Hebrides. The public ground

necessarily devided. Planting never became general in

Perthshire till after the middle of the eighteenth century.

The county is now distinguished by its extensive tracts of land,

common pine, and other trees, and by the enclosure of oak,

broad-leaved trees, from the opening of the beginning of

the century, which has been continued in the same

manner, and been so extended in the same manner as

the proprietors, by the crown, and the tenure of

succeeded.

county than in all the rest of Scotland. The counties of

Pun

bass, Argyle, and East Lothian, contain the

Perth.

The copse of oak is cut once in twenty or twenty-

four years. The two rare trees of the most promising appearance and of the

test figure are the oak and the pine. The oak is sacred to the

God of the sun, and is an emblem of immortality. The pine is

straight. Yet as coppice wood is the object, straight trees

injure at least. Scotch oak has been found in general too close in

the grain to be cut into planks, the sides of ships, and even for the same

reason it is found to snap when used as ribs to a ship. In its cleavage,

it is so delicate as to break to pieces upon the touch. Being a

wood, which will not split, it is not subject to

injurious

loads.

Before agriculture improvement arrived as well understood

as it is of late, or occupied so much of the attention of

all, and especially in the

country, many moorish tracts of lands were deemed

inable of cultivation. But rocks, or other obstacles, were

levy as equal to their being planted. Proprietors, even in the

Carse of Gowrie, and some of the western counties of

Dumfriesshire, did not consider the whole country as worth

the expense of cultivation. This must be considered as a

principle, about thirty years ago, planted the waste lands of their

property of necessity, or as a mere

in the

impulse, that this soil, by being wrought, will make good arable

land, and will be more productive if cultivated. By

STATISTICS

of agriculture.

I. GEOGRAPHICAL STATE AND CIRCUMSTANCES.

The county of Angus is bounded on the west by the districts of Forfar and Glamis, on the north and east by the districts of Kincardine, Mar and Mearns, and on the south by the districts of Fife and Kinross, and on the east by the sea of the Firth of Forth. The length of the county is about 45 miles, and its breadth about 30 miles, including its most distant extremities.

2. ANGUS OR FORFAHIRE.

The land is not very fertile, and consists of great heaths and moors, interspersed with a great number of peat bogs. The soil is generally dry, and the winters very severe.

3. SYSTEM.

The system of agriculture is much improved, and the improvements are well understood and generally practiced. The land is divided into farms of various sizes, and the farmers are generally well acquainted with the principles of agriculture.

4. INCOME.

The income of the county is derived from agriculture and from the fisheries, which are very productive.

5. OCCUPATION.

The chief occupation of the county is agriculture, and the farmers are generally well furnished with the necessary implements of their trade.

6. FISHERIES.

The fisheries of the county are very productive, and the catch is generally well preserved.

7. SALTING.

The salt is obtained from the sea, and is sold at a fair price.

8. WOODS AND PLANTATIONS.

The county has a considerable quantity of wood, and plantations are being established in various parts of the county.

9. RURAL ECONOMY.

The farms are generally well managed, and the farmers are generally well satisfied with their situation.

10. CONCLUSION.

The county of Angus is well supplied with the necessaries of life, and the inhabitants are generally well satisfied with their situation.
Agriculture of Aberdeenshire.

1. Property.

In few hands larger estate 40,715 acres, the rest in eighty or more hands.

2. Buildings.

Some old farm houses still remain, built of stone and turf, and some others are more modern, two storeyed, with a parapet and new farmyards are erected on the most improved plans, with commodious dwelling houses. No man can be said of the cottages, which have undergone very little alteration in structure, for a long space of time. The habitation of the farmer may have advanced in elegance and accommodation a hundred fold; but the cottager still lives in the same simple kind of frame, by which he has been put up in the most primitive institution. A cottage built of stone and turf, or more generally of straw and turf, consists of two rooms, in which are the habitations of the house, of two apartments divided by the furniture. In each of these there is a fire-place and a window. The fire is still wood, and the turf or straw is laid on it. The seats have four, three, two, or one panes of glass. The house may be about thirty feet in length, and thirty feet in breadth. The walls are built of turf, and the doors and windows, and all the openings, are renewed from time to time, and tied firmly with straw ropes. The walls have cut the appearance of a low hay-stack. Every house contains a little garden, where many of them bestow much care, and show little taste, in its cultivation. It generally contains various kinds of cabbages, onions, carrots, &c., for the pot, they frequently have row of potatoes, and sometimes of turnips, and other flowering stables. Some of them devote the walls of their houses with honeysuckles, or with ivy; and in some instances, thistles and daisies.

The furniture of a Means cottage consists, in general, of two chests, a bed, a couple of stools, and a long table, separate between two apartments; one or two wood-chests, a chair; a rack for holding hooks; a set of drawers, utensils; an iron pot or two for cooking the victuals; a girdle, or heating iron, for toasting the bread; and a few dressing tables, supplied with drawer or three steps, an ass on chairs or stools, and a press or cupboard for holding the crock or plate, and sometimes the clothes, at times, the whisky bottle. A tea equipage, on a small scale, has also of late become an indispensable article of cottage for-

3. Occupation.

Abarle farms of various sizes; many small; some 400 or 500 acres. Hill pastures and hill meadows, and meadow lands of the rent farm occupies 20,000 acres. Leases formerly set on periods of six years, three years, and two years, are now extended to life-tenure; at the term seldom exceeds nineteen or twenty-one years, unless great improvements are expected to be made in the lands. The land is let under judicious rotations, in which either turnips or root crops are half the year, and the pasture is the other, or the have seldom less than five pounds worth of clothes, and yet, in many instances, the people are found to be as well-clothed.

and the number of connoisseurs circles near its root, viz. 293, showed it to have grown and increased in size for 229 years, heads the time that it is continued stationary. Its tree was described as a very large and remarkable tree, and it is said that any that had ever been imported from the north of Europe.

The new trees are not yet matured, but it is believed that they will be much more valuable than the old ones, as they are nearly six feet in diameter, or which are superior, in point of produce, to any of the seeds imported that was ever imported into any place in Great Britain.

III. Improvement.

Trees and shrubs have already mentioned: within three miles of Aberdeen, above 900 acres trenched; some acres paid 50£.

Woolen, linen, cotton, now extensively manufactured. Knitting of its kings and spinning lint formerly common, but little attended to since the introduction of machinery.

7835. NAIRNISH and MORAYSHIRE, forming together 515,000 acres of mountainous surface, and some narrow arable valleys, are included in one survey. The climate along the Moray Frith has always been noted for its mildness, which is partly owing to its locality, and partly to the general prevalence of a slight wind from the north. The mountains are higher, more severe and higher than in the north, and the freestone, as is found, but the two are not worked at all, and of the others, only the freestone, to any extent.

(Leslie’s General View, 1810.)

1. Property.

2. Buildings.

3. Occupation.

As in Rinfancashire; but the arable lands being generally flat and level, the improvement of them is more prevalent. It is a singular fact, that in an island in a lake, Loughmaben, in this county, there is a whole farm of about 400 acres, more purely pastoral than any where else in Britain. This island contains a fortress, and the river running through it is divided by a barrow, which has stood without any repair, distinguished a very few of the most respectable harbors and landing places in the north-east of Scotland. The county consists of almost every kind of soil, at first, but is very valuable. Where the soil is more barren, the Scotch pine is generally the best quality. A remarkable tree, at Invercauld, was cut down about forty years ago; and the turnips of rutabaga, or turnip turnips, which are so common, but little attended to since the introduction of machinery.

The cultivation of turnips, as a food for cattle, was first introduced into this district, from the county of Norfolk, by the late Mr. Cooper, about the year 1774.

When the artificial glasses and herbage plants were introduced by the great landowners, when the new common country, the operations of the flowers. Few flowers or plants imported from England; a few natural woods, and extensive artificial plantations. In general it may be observed, that in this, as in the other counties of the north, every improvement has been attended with success, and the implements have been tried, and the experimenter even promises an additional supply of coal and iron, the iron of wrought iron, and the iron of wrought iron, in order to improve the quality of the country and the landscape, so as to meet the demands of the time. However, there is no good deal of holly carried on along these roads, and in the Moray Frith.

The knowledge of the state of agriculture in various districts, content, or petty. Minerals of various kinds are seen (Mackenzie’s General View, 1810.)

7834. The shires of ROSS, NAIN, and CROMALY are three adjoining mountainous districts, containing 2,041,800 acres. The soil is in general light, found, but only building-stones and lime are worked out, without culture. The rest, in some favourable situations, it is said, had been found of one pound weight; but they resemble in general the wild kind, having a long root like a small radish, of a brownish colour, and a pointed leaf. Some of the coarse cabbages were also distinguished among them. Both were used as pot-hay at the tables of the country people, on which account they were sometimes raised in their gardens. When they grow, and come to seed, this kind of joint cattle, cattle, are very rotten, and not the best, they consider the small hills and cattle, which are generally bought by inferior dealers, as too resolute and impatient for feeding well. They prize the native low country breed to the large -ows, as they are most easily managed; and in their hands, have the largest numbers of fowls, and raise good eggs, and pay better in proportion to the goodness of their keep.

Every year, for the last thirty years, has increased in size, and that by good keeping; and it is two or three times its former size, and double its former size. It weighs at least double its former weight, and is of the same kind. Some breeders are also decided of opinion, that wherever a landed proprietor breeds such cattle, he will not do well, but tied up, and allowed to feed loose, in order to get gentle-ex. There is something inbred in his food; that the second-year he may be forced to keep his cows to which he is tied, and when he has tied up, he will be sickly, or not thriving.

The soil is the bed of a mixed breed. Horses are scarce, ponies, or purchased from Clydesdale. Poultry very common; beef and mutton for the Aberdeen and the Landmark markets. Red or yellow numbers. Brachmus, and rose on the hills of Cromar.

1104. Denny’s estate.

County long celebrated for its woolen manufactures. About 1650, many persons were engaged in the manufacture, had a daughter, who married Lieutenant Cadogan of Cromwell’s army, who afterwards was made a peer, and from whom the name of the place is derived from the Craigs in Lass Colgan, Oxbury, Holland, C. J. Fox, and the heads of the other noblemen.

Woolen, linen, cotton, now extensively manufactured. Knitting of its kings and spinning lint formerly common, but little attended to since the introduction of machinery.

7836. Statistics of agriculture. Part IV.

The county of Aberdeen is distinguished beyond any other county in Scotland, from the variety and fertility of its gardens, which cultivate the lands in the neighborhood of that city, and which are now the favorite subject of every attention, and generally limited. There, in fact, are kitchen gardens, seatme, and nurserymen. They face all sorts of streets for the inhabitants of the city, and are among the largest and most extensive used for the country at large, and nurseries so extensive, and so carefully managed, that some of the proprietors in the county, and the owners of villas near the town, they export considerable numbers of plants to England.

A few good private orchards, the largest that of Ferguson, of Pitten, of ten acres. The site of it, nearly 600 years ago, consisted the Abbey of Dees, founded in 1214, and the garden belonging to the monastery. It is a striking proof of the luxuriance of these gardens, skill in the raising of fruit-trees, that when Ferguson was laying out his own orchard, he found in the old garden, to be rich soil above three feet deep; secondly, a well-panned castaway of granite; thirdly, a bed of pure sand, one foot deep: fourthly, another castaway of granite; and below the soil, a considerable depth of rich mould. No greater precaution could have been taken, than to bring the best stones from being, by incised into a cold or wet soil.

The vegetable of the garden, occupy nearly 100 square miles, in some places very thickly planted, and in others raised by the special direction of the gardener. The top soil of every one third has been both enclosed and planted; one third has been raised by nature, without either enclosing or planting the greater part of it, and the remainder, enclosed for for purposes of keeping out the cattle, and been stocked, with wood, rock, and flower, and a large number of shade trees planted by the rocks, who, by some instinctive impulse, carry the cones of the New and the old wood, and the branches of the same trees for their orph- ing, at a remote period; when the seeds contained in these cones became trees, in which they may build their nests. This supports the idea that in the rocks is more anciently formed earth, with a view to a firm surface to break the cones on; and so that the seeds may remain, also, be injured by the heat of the sun, which enables the rocks to find the seeds without- Our ancestors were more so and so, that the proprietor need only enclose an extent of hilly ground, and thus shut out the cattle. The wind and the rain would carry away the cones in time, without the sheep doing so.

But while the native woods grow very irregularly, it is found prudent to assist nature, by sowing the seeds of the better kinds of trees, and a number of seeds of the trees which are wished to be reared in the vacant spots of the South. The wood consists of Scotch pine; it grows slowly at first, but is very valuable. Where the soil is more barren, the Scotch pine is generally the best quality. A remarkable tree, at Invercauld, was cut down about forty years ago; and the number of connoisseurs circles near its root, viz. 293, showed it to have grown and increased in size for 229 years, heads the time that it is continued stationary. Its tree was described as a very large and remarkable tree, and it is said that any that had ever been imported from the north of Europe.

The new trees are not yet matured, but it is believed that they will be much more valuable than the old ones, as they are nearly six feet in diameter, or which are superior, in point of produce, to any of the seeds imported that was ever imported into any place in Great Britain.

III. Improvement.

Trees and shrubs have already mentioned: within three miles of Aberdeen, above 900 acres trenched; some acres paid 50£.
**Book I. AGRICULTURE OF SUTHERLAND.**

1760, it may safely be concluded, that agricultural knowledge was primitive in this county. The cultivation of the soil, which has been practised in these counties, and in other parts of the north of Scotland, and in parts of the South of England, has been, with few exceptions, the same in the two countries for a great number of years. The primitive state of farming has been, in some measure, preserved in Sutherland, from the influence of the remote situation of the county, and the unfavourable climate of the country. The soil of this county is generally thin, and the crops are, consequently, short and coarse. The land is divided into small portions, and the crops are, therefore, of little value.

2. *Buildings.*

The old highland tenantry are universally ill accommodated. The Auchincruive estate, on which I had the first chance of notice, is the finest of the kind, and the most comfortable in the county. The farm-houses are of stone, and the offices and homes comfortable and commodious. The improvements in this county are so numerous, and the improvements in the town, from the prize market, are so great, that it is difficult to estimate the value of the land, or the value of the improvements. The value of the land in this county is very high, and the improvements are very extensive.

2. CAITHNESS.

203,650 acres, three eighths of which is deep, mossy, and flat moors, covered with heath; three eighths mountains, moor, and some hilly pastures; and the remainder in cultivable land, lakes, &c. There is very little wood, either natural or artificial; but excellent time and freestone. On the whole it is one of the coldest, wettest, and most dreary counties of Scotland; and is in no remarkable way, except that the soil is very good, and the climate is very cold.

3. SUTHERLAND.

1,572,000 acres, chiefly of mountain and moor; and a climate about a fortnight later than that of Edinburgh. The greater part of the county is the property of the Marquess of Stafford, whose astonishing, masterly, and successful improvement of the country has been repeatedly detailed in Loch's work. The Marquess of Stafford has been a great improver, and again recur. (Henderson's General View, &c. Loch's Improvements of the Marquess of Stafford, 1819.)

The state of the Sutherland estate has only lately undergone that change which began to operate in England as far back as the reign of William the Third. The state of the estate is that of a well-ordered and thriving county, and the improvement of the property has been carried on with the greatest care and attention. The estate of the Sutherland estate has been divided into small portions, and the improvement of the property has been carried on with the greatest care and attention.

The principal farmers in the county under review are intelligent, and have been engaged in some time in the improvement of the property. The principal improvements in the county are those of modern agriculture, as practised in the southern counties of Scotland, and are of great importance, as it has been the means of improvement, and will, in a much greater extent than is done to the south, and, of course, much better for the improvement of the county, and for the benefit of the people. It is remarkable that the principal improvements in the county have been the enlargement of the township of Thurso, and of various other schemes, and which are still in progress.

1809 was a year of small rain, and the crops were but small. The principal farmers, with few exceptions, are industrious, sober, and thrifty, and have, unfortunately, a turn for litigation, and expend more money than they ought to do in law, by which their circumstances are often injured.
must be formed of the most durable materials, and the best workmanship, to resist the impetuosity of the currents. Nothing will set this in a lasting point of view, as to state, that upon the projected road back and forth, a distance of forty-six miles, three bridges of three arches each, two bridges consisting of one arch of four feet span, two of twenty feet span, three of twenty, four, six of eight, and one of twelve, besides many others of inferior dimensions, would be required. On the Stafford

estate excellent inns, often combining farriers, have been built in a number of places at an enormous expense. As an example, we may refer to one (fig. 1152.) containing an outer kitchen and servants' store (a), with a pantry (b), two bed parlours, with movable partition for great occasions (c), principal entrance (d), a small parlour (e), small room (f), kitchen (g), back kitchen and servants' stair (h). Over are five bedrooms, and nine garrets for beds.

Thus, in the course of twelve years, has the county of Sutherland been intersected, in some of its most important districts, with roads, in point of execution superior to most roads in England. And owing to the equally praiseworthy exertions of the counties of Ross and Inverness, on the one hand, and of Caithness on the other, the same perfect means of communication now exists, from the borders of Inverness to the town of Thurso upon the North Sea.

Few districts of Scotland possess so small a proportion of land fit for cultivation, compared with its extent, as Sutherland; and probably to the year 1811 but even a small portion of that was brought into cultivation. Each shore line is fringed (if the expression may be used) with a narrow border of ample land, which, on the south-east coast, extends from a few hundred yards to about one mile in breadth; the interior consists entirely of mountains.

The lands were let to tenants, as in Ireland, till in latter times, when a certain district was let to the whole body of tenants resident in each "town or township," who bound themselves, compactly and severally, for the payment of the whole rent. This land was held, as expressed in Scotland, "ten per," or like common field land in England.

The effect of this arrangement was to scatter thickly a hardy, but not an industrious race of people upon the glens, and over the side of the various mountains, who, taking advantage of every spot which could be cultivated, and which could with any chance of success be applied to raising a precarious crop of inferior oats, of which they looked their bread, and of hay, from which they distilled their whiskies, added little to the industry, and contributed nothing to the wealth of the empire. Impatient of regular and constant work, all the heavy labour was abandoned to the women, who were employed, occasionally, even in dragging the harrow to cover in the seed.

To build their house in their pastures for food, or to perform any other occasional labour of the kind, the men were ever ready to assist; but the great proportion of their time, when not in the pursuit of game, of illegal distillation, was spent in indolence and sloth. Their huts were of the most miserable description. They were built of turf, dug from the most valuable portions of the mountain side. Their roof consisted of the same material, which was supported upon a rude wooden frame, constructed of crooked timber, taken from the natural woods belonging to the proprietor, and of moss or turf from the peat bogs. The situation they selected was uniformly on the edge of the cultivated land, and of the mountain pictures. They were placed lengthways, and sloping with the declination of the hill. This position was chosen, in order that all the fifth might flow from the habitation without further exertion upon the part of the owner. Under the same roof, and entering at the same door, were kept all the domestic animals belonging to the establishment. The upper portion of the hut was appropriated to the use of the family. In the centre of this upper division was placed the fire, the smoke from which was made to circulate throughout the whole hut, for the purpose of conveying heat into its farthest extremities. The effect was to cover every thing with a black gloomy soot, and produce the most evident injury to the appearance and eye-light of those most exposed to its influence. The floor was the bare earth, except near the fire-place, where it was evenly paved with rough tiles. It was never levelled with much care, and it soon wore into every sort of inequality, according to the hardness of the respective soils of which it was composed. Every hollow formed a receptacle for whatever fluid happened to fall near it, where it remained until absorbed by the earth. It was impossible that it should ever be excepted; and when the accumulation of fifth rendered the place uninhabitable, another hut was erected in the vicinity of the old one. The old
raffens were used in the construction of the new cottage, and that which was abandoned, formed a valuable collection of manure for the next crop.

The intersection of the potato, in the first instance, proved no blessing to Sutherland, but only increased this state of retch-
edness, insomuch as its cultivation required less labour.

So long as this system just described remained in full force, no attempt could be made to improve or moderate the situation of these poor people. To better their condition, however, to raise them from such a state of continual poverty and occasional want, to supply them with the means, and to create in them the habits of industry, was, and is the bounden duty of the owners of every such property. And it was not less their duty to do, because the same arrangement which was calculated to produce this salutary effect was at the same time the best suited to increase the value of their property, and to add to the general wealth of the community.

The fundamental principle of agricultural improvement in this case was derived from no speculative reasoning, but from what has actually taken place in a different but similarly circum-
stanced part of the kingdom.

It is well known that the borders of the two kingdoms were inhabited by a numerous population, who, in their parents, mothers, and general structure of society, bore a considerable resemblance to the proprietors of the estates in the highlands of Sutherland. When the union of the crowns, and those subsequent transac-
tions which resulted from that event, rendered the maintenance of that irregular population not only unnecessary, but a burden to the proprietor to whom the land belonged, the people were removed, and the mountains were covered with sheep. So that it had been for a length of time proved by the experience of the stock farmers of those mountain tracts which comprise the northern districts of England, and the southern parts of Scot-
land, that such situations were perversely suited for the main-
tenance of this species of stock. Taking this example as their guide, experience had still further proved, that the central and western highlands of Scotland were equally well calculated for the same end. Reasoning from this success, and observing that the climate of Sutherland, owing to its vicinity to the ocean, and to its being considerably intersected by arms of the sea, and much more moderate than the latter districts, it was early concluded that this county was even better fitted for this system of management than the heights of Firthshire and Invernessshire. The inferior elevation of its mountains contributed still further to this effect, and held out every encour-
agement to adopt the same course which had been pursued with such success in both parts of the kingdom.

The property of converting the mountainous parts of the county into sheep-walks was in this was rendered evident, provided the people could be at the same time settled in situations, where, by the extinction of their homesteads, they could obtain a decent livelihood, and add to the general mass of national wealth, and where they should not be exposed to the recurrence of those privations, which so frequently and so terribly affected them, which situated among the mountains.

The principle of providing for the lower class of tenants by the establishment of fisheries was thus derived. It had long been known, that the coast of Sutherland abounded with many different kinds of fish, not only sufficient for the consumption of the county, but affording also a supply, to any extent, for more distant markets, or for exportation when cured and salted. Besides the regular and continual supply of white fish, with which the shores then abound, the coast of Sutherland is annually visited by one of these vast shoals of herrings which frequent the coast of Scot-
land. It seemed as if it had been the natural design of nature, that the system for this re-
source should be in order that it might bear its suitable importance in contributing its share to the general stock of the county, was, to con-
tinue the mountainous dis-
tricts into sheep-walks, and to remove the inhabitants to the coast, or to the valleys near the sea.

Several sea-
ports were improved by the construction of piers (fig. 1133) and breakwaters (6); and the plan of a town begun. Formerly the inn, church, post-office, market-
place, and other public buildings, were erected by Lord Sutherland, and the most liberal encouragement was given by orders of money, grants of land, and little or no duty, &c., to fisheries, manufacturers, tradesmen &c., both on a large and small scale, to come and settle there. Such is the policy of Lord Stafford's opera-
tions, in which he has expended, and continues to expend, independently of the cost of improvements on the manor (fig. 1134.) and park of Dunrobin, immense sums. Happily the success has equalled the most sanguine expectations; and for the very interesting details of execution, or limits oblige us to refer to the work of Loch, which, as already observed (1795), we consider of very singular agricultural interest.
STATISTICS OF AGRICULTURE.

PART IV.

7857. INVERNESS-SHIRE. Upwards of 7,000,000 of the farthest mountains in the country, contains about 12,000 acres, and comprehends many islands, which are scattered far and wide. The hills and moors were formerly covered with fir woods, the remains of which are dug up in all the moors in abundance. The climate is rainy, mild on the west coast, but less so on the east. The soil of the vales is loamy or gravelly, and the stone or sandstone; but loam, iron, and clay, have been found in different places. The county is remarkable for its native fir woods, and for that stupendous national work, the Caledonian Canal. Improvements were first commenced about Inverness by Cromwell's soldiers. Robertson's General View, 1810, 11.'

1. Property. In few hands; largest, Lord Macdonald, of the Isle of Skye, the barony of Lochalsh, who resides on the coast of the mainland, farms are large, and, in some cases, reckoned by miles, or by thousands of acres. There are no supposed to carry.

2. Gardens and Orchards. To be found in a few places; and some old pear trees, planted by the old barons, are still in a bearing state, and one or two others. There is an excellent fruit and forest tree noted at Inverness.

3. Woods and Plantations. The Scotch pine, for the most part, took possession of the southern districts, and are extensive in.stations; but the pine, and even the birch, have been found in different places. The county is remarkable for its native fir woods, and for that stupendous national work, the Caledonian Canal. Improvements were first commenced about Inverness by Cromwell's soldiers. Robertson's General View, 1810, 11.'

4. Livestock. Cattle are of the Skye or Kyle breed, usually, however, known as the Inverness breed, and are a good size, and very hardy. The district south of the River Livestock is very limited, although the soil is rich, and productive of better of excellent quality. The district of the highlands is noted for its wool. The breed of sheep is also noted for its wool. The breed of sheep is noted for its wool. The breed of sheep is also noted for its wool.

5. Marketable Produce. The leading article of which is used for fencing and the carriages of horses, and the bark for paper and other purposes.

7858. ARGYLLSHIRE. 2,357,000 acres; the eleventh part of Scotland, and the thirtieth of Great Britain, and nearly the whole of the Scottish kingdom from A.D. 503 to the subjugation of the Picts in 845. The surface of the country is rough and mountainous; in the northern parts ' Alps piled on Alps hide their heads in the clouds. The climate is moderately mild, very moist in the vales, and on the coast, and very dry in the southern districts. The soil of the vales is loamy, and the minerals are copper, lead, iron, coal, stonbrack, freestone, granite, limestone, marble of several different colours, slates, &c., but the two first are not worked at present. There are numerous bays, inlets, and lakes, in some of which excellent fish is caught. The county is in no respects remarkable in an agricultural or manufacturing point of view, and is noted for its sheep and the cattle and sheep there; and there are some oak coppices and artificial plantations.

I. Property.

The lands of forty-one proprietors; highest rental 18,000£, and assessed 312,500£. A great many tacksmen. Those of Islay are said to " combine the spirit and elegant hospitality indigenous to this county, in accuracy in dealing punctually in paying, and all the useful qualifications of first-rate low country farmers. It must not be forgotten that obtaining the order of tacksmen, that they are exceedingly useful, and often necessary for maintaining good order and against the infernal. Without their aid, the efforts of the clergy and officers of justice would be painful and unavailing. Therefore, not to be rashly banished, were they to be viewed in no other light than merely as subsidiary to the police and civil administration of the Isles."

2. Buildings.

Houses throughout the Hebrides are either houses of tocksmen, tenants, or subtenants. Tacksmen's houses, though still far behind those of considerable farmers in the principal counties of England and the lowlands of Scotland, are, however, in general, beginning to be tolerably decent and comfortable; and on the whole the large estates of them have been made within the last twenty-five years. Most of them are made of brick and lime, and one or two stories high, and furnished with kettles and other accommoda-
tions. In many instances, indeed, if the houses are still in a deplorable state, it is because they are rapidly improving; and that order of farmers exist for half a century longer, their houses will, probably, be as commodious, and their offices houses as judiciously planned, as those of the same description of persons in the Lowlands of Great Britain.

The houses of the occuprying tenants, are generally speaking, wretched hovels, and those of the subtenants, naked and miser-
able description. Peasants describes them as habitations made of loose stones, without chimney or doors, excepting the faces opposed to the wind at one or other of the apertures permitting the smoke to escape in order to prevent the pains of asphyxiation. Furniture corresponds; a pot-bag hangs from the middle of the roof, with a pot hanging over a gratesless fire, filled with fire which may range from a small fire to a sort of vigorous life; the inmates, as may be sup-
posed, lean, withered, diseased, and snuffed- dried.

The hovels of the yeomen are in some degree, realises a far in the Hebrides, even at the present day. The whole picture is of the most miserable, both in plan and execution, that they deserve mention only as proofs, that a sensible and sagacious race of men may, by a combination of unfavourable circumstances, not only be gradually brought to ignominious, which, to their equals in other countries, would seem irredeemable, but also, in the course of time, may lose the power, and even the will of subsisting thereby. Tacksmen's houses of the 16,000 cottagers of the Hebrides live in hovels which would disgrace any Indian tribe; and many of them are found on islands of the first rank in point of population and extent. At least 7000 of the natives of Lewis (for instance) know nothing of a chimney, table, glass window, horse floor-
ing, or even hearth stone, by their own experience at home; and what we call their furnitures, as may be imagined, were-laid and scanty beyond description, corresponding with their station.

In the woods of the park at Bluff were formerly fine specimens of Hebridean cottages and other fancy wooden buildings (fig. 1135).

3. Occupation.

In estimating the size of Hebridean farms, the common plan is to add to three leading objects: first, the number of live stock which the farms in question can maintain; secondly, the number of both of which can be eaten, or of ploughs requisite for their tillage; and thirdly, the quantity of hay that can be made upon them.

Generally, whether for sheep or cattle, must gradually be enlarged; and keep, or merely agricultural farms, must as naturally become limited and confined in all parts. The hay on many of the great farms, and sometimes the corn on arable grounds, is obliged to be kept by hanging on poles, trees, or rods (fig. 1136), as in Sweden.

4. Implements.

They are peculiar to the Hebrides, as the caschern or crooked spade (fig. 1157), which, in two parishes in the Isle of Lewis, entirely supersedes the use of ploughs in the raising of potatoes and vegetables. This instrument is, that it enables the operator to work in muddy or boggy places, where horses can, or could not, possibly be inac-
cessible to the plough. Many districts of Harris and of Skye would be completely, and yet inefficiently, cultivated without it. Its importance is, that it makes the common trenching spade, or to any tool which penetrates the ground perpendicularly, a very great, and sometimes fatal, exhausting factor; both from the struggle which the garden yields in, and the length of the horizontal clod which its powerful lever enables him to turn over.

The clod, or sickle plough (a sort of parting plough), is used for the cultivation of old land, or the tough roots of plants, which would otherwise greatly impede the passage of the plough.

5. Arable Land.

Tillage is in its infancy over the Hebrides, in all the isles northward of Mull excepting half a dozen farms in Skye, a few in Mull, and one in the small island of Uist. In Mull, a little lately done in Lewis, near Stornoway, and by Campbell, of Ilay, on a small island between the mainland Uist and Harris. These improvements have been carried on within the last fif-
ten years, and would be rather ludicrous than useful to describe the til-

Ilay, Colonies, and part of Skye, to improved systems of tillage.

It is not to be expected that much should be done in garden-

ing, in a district so far removed from the greater part of the proprietors are non-resident, nor is the climate suitable for that art. The winds are too violent, and the sun too shy of showing his face. Until trees and other sorts of shelter become, therefore, more general, the gardens and orchards of the Hebrides will probably be little more than an empty name.

In the sixteenth century it appears most of these isles were covered with woods, and even so late as Bishopman's time. One exhilarating remark, however, occurs to the traveler who traverses those bleak and woodless regions, amidst the moun-
tains which he sees in Buchan and Moray, namely, that where trees have formerly grown they will grow again, and that any regions which were once sheltered and adorning by the hand of nature, may still be in a far higher de-

8. Livestock.

The ancient Hebridean breed of cattle is now no longer to be found. Some persons imagine it to be the Skye, others the Mull, and others again the Lewis or Long Island variety. A person accustomed to accurate observations on cattle, can easily distinguish those different breeds from one another, and all of them from the largest breed now introduced into Ilay, Colon-
COMPETITORS OF THE GRASSSEEDS.

8760. THE ORKNEY ISLANDS are thirty in number, and contain about 384,000 acres.

Many of them are uninhabited, and only aff ord pasture for sheep, or serve as sites for military camps. The soil is peaty, and clay, and gravel are found in some of the valleys. The soil is seldon more than six feet deep, and of sandstone. The isle of Rousay is a very backward state. The plough used is generally the single-tiller one; the mansion is chiefly sea-weed, and there are but few gentlemen's farms. The meadows are in the most part covered with heather, and the soil has never been improved. The plan of husbandry is to till very slow and hard, and to make a single crop of oats followed by three or four years of fallow. As the ploughs are selden more than six feet deep, and the soil is often covered with heather, the land has never been improved.

8761. THE SUTLAND ISLES are about eighty-six in number, of which forty are inhabited; the whole contain about 48,000 acres, nearly equally divided between pasture land and arable.

The climate is very mild, and cold northern and eastern winds are extremely prevalent. Winter may be said to occupy full six months in every year, and the harvest is not over in September; the crops are generally spoiled from tempests. There is a great diversity of soil; often deep moss on a bottom of sand, though sometimes the moss or peat is only a foot thick on a bed of drift stones; in many places it is overgrown with heather, excepting juniper, and occasionally a few mountain ash; the rocks are usually bare, very stony, and little inclined to digging, or deep into the ground. Turf and peat are used for fuel. The soil is seldon extensive, and of little profit. The few sheep which are present are of a small size, and rather exceeding ten hands in height, and are celebrated for their speed and ease. The cattle are all small, very thin, though they feed well, and weigh three quarters of a hundredweight, in proportion to the size of their horns; they give generally no milk, and of the remaining flesh of the cattle are also very small, though they feed well, and weigh three quarters of a hundredweight, in proportion to the size of their horns; they give generally no milk, and of the remaining flesh of the cattle are only two or three months old. The fruit of which they are composed double that quantity. The nutrition of the Sutherland islands is limited to between 20,000 and 30,000; the wool is very short, and though generally of a fair quality, is not sold for that purpose; it is only bought as yarn by the farmers for their own use. The cattle are well supplied with fish, and have to crop roots and plants of every description, and is a mortal enemy to every species of growing woods.

Growing crops is very uncommon, excepting potatoes, which are generally planted in the south of the Hebrides, and occasionally, and but of food in winter and spring for those which they possess.

The chief crops are oats, barley, and potatoes. The former of these is the very best possible for the country to support, and may, by due attention to the cultivation of the ground, be made to yield a plentiful harvest. The breed of sheep already recommended and described may be improved, and reared to twice their present numbers, without seriously injuring the agriculture or other improvements. The result may be a vast accession of wealth and food might accrue from breeding a comp tent number of hogs, for which these islands abound, to potatoes, are extremely well adapted. But all these improvements must go on progressively, and be attended to by the advice and direction of the train of other agricultural and economical improvements.

Roads, canals, and navigation. In Russia, Poland, and Sweden, in a very retrogressed state. No great railways or canals. No equal portion of these has been constructed. The Russians and Poles have not the means of transport and canals. The numerous and most uncultivated people of Russia and Poland, possesses so many in their resources as to create a great popularity. The Székely is, among other causes, a principal source of poverty and depression of the people. It makes the little money which is procured in agriculture and trade, and drawn in exchange for gold, cattle, and the other productions of the country, considerable portion of it is to the wealthiest dealers. Kep. in Hungary and the Hebrides manufacture, and is in an advanced state. Maccoll, of Staffa, is distinguished for his attention to agriculture, and for the improvements accordingly preserved for his kelp a character, which enables him to demand a higher price than any of the other dealers in the Hebrides obtain. This results principally from its being sold early in summer, its being daily attended to, and in the carriage and drying of the result. It is especially arranged to dry, and is then sold at a very low price. The Maccoll's scedens are the most common. Strange fishes, marine shells, and even exotic frogs, are sometimes eaten on these islands. As a rich dish, and are considered as a delicacy in the Hebrides. The corbs (Corvus Corax) is a dangerous enemy to the newly dropped eggs. The inhabitants on the coast live by fishing, and making kelp. The staple article of diet on the other parts of the islands, is whole, which used formerly to be turned into meal, but is now consumed as such, and as they are never tempered (except when actually ill of the scall), they are, in every respect, as wholesome as bread. The kelpek on Sheep Husbandry in Orkney, in Econ. Hist. Soc. vol. iv. p. 593.
milder and more equable than that of England; and with the dry soil, as Wakefield remarks, is admirably adapted for pastureage and occasional arsem. The agricultural exports of Ireland generally, we have already given a condensed account (597), and shall here submit some brief notices as to each county. These undoubtedly present a degree of sameness incompatible with much interest or instruction. There are agricultural surveys of both a statistical and a descriptive nature, whose results are too much identified with the interesting work of Wakefield, and some more recent statistical writers and tourists. When the first edition of this Encyclopædia appeared, the statistical portion, as far as respects Ireland, was objected to in the Irish Farmer's Journal, as representing the agriculture of Ireland a being in its infancy, stale. We have noticed this in the Gardener's Magazine (vol. iii. p. 229), and have, since then, used every exertion in our power to procure later information from books or correspondents, but without much success. In fact, from all that we have been able to collect on this point, that even now statistics of the agricultural state of Ireland is not materially different to what it was in the time when our text-book (Wakefield) was first published.

8753. DUBLIN. 228,511 acres; sixth in mountain and waste, a tenth in buildings, roads, rice, etc., and the remainder in arable and pasture. Brit. Edin. Gaz. 1827.

The climate of this county is drier than that of some others; east and north-east winds are less frequent than in England, but showers from the west are frequent; Average number of dry days in Dublin for ten years, 172; or more frequent than in any part of Ireland. The soil is generally shallow, and the substratum almost universally a cold clay. There is very little turf bog in the northern parts, but some considerable tracts among the mountains in the south. Freezant, granite, Irish slate, ophite, porphyry, and some beautiful pebbles, including sandstone, limestone, and granite gravel, abound in various parts. The iron ore is not of much account; the manganese, which is not inconsiderable, is chiefly near Wexford. The copper formed nearly 7865. the Irish. In 1801, as being in the same county, come and after the same, which is the description of the whole of Wakefield's Ireland. We have noticed this in the Gardener's Magazine (vol. iii. p. 229), and have, since then, used every exertion in our power to procure later information from books or correspondents, but without much success. In fact, from all that we have been able to collect on this point, that even now statistics of the agricultural state of Ireland is not materially different to what it was in the time when our text-book (Wakefield) was first published.

8755. WICKLOW. 500,000 acres, in great part mountains and bogs, and without inhabitants. (Fraser's Survey of Wicklow, 1801. Sup. Encycle Brit.)

The climate is so mild, that the myrtle flourishes in such profusion; its crystalline robe is frequently used for making stable brooms. The common laurel, Portugal laurel, and Arbutus attain a great size, and can be seen as well in Wicklow as in any part of England. The raspberry, the bilberry, and the ling are found in abundance near the sea-coast of Wicklow, the climate of which is equally temperate. The fruit of the strawberry is in Mr. Wakefield's description of that of the rest of Ireland. This is the only part of that country where the gooseberry grows plentifully. Metallic ores are supposed to abound; copper and lead have been worked, and gold has been found. There are no navigable rivers or extensive lakes. Some of the streams precipitate themselves from considerable heights, forming picturesque cascades; the most remarkable one is at Powerscourt, where the water falls from a height of 300 feet. Landed property in the county of Wicklow is large in extent.

8756. WEXFORD. 597,730 acres, mountainous on the north and west, a light soil and tolerable cultivation on the east, and in other parts sterile clay, unimproved by culture. (Wakefield. Fraser's Survey of Wexford. Sup. Encyc. Brit.)

The climate is mild and favourable to the growth of timber, which abounds here more than in most counties. There are some extensive forests in the county. The landed estates are large, from 6000 to 10,000 acres, and in many cases of various sizes; but there is little here that is common in other parts of Ireland; nor are there any rich grazing farms. Dairies, at which the principal agricultural production is carried on, and generally under fraud management. The cows themselves are of a very inferior description, and the same character belongs to their sheep, which forms a very inconsiderable part of the live stock. In their modes of cultivation, however, if not more advanced than in many other parts of the island. The baronies of Wexford and Barfge have been long noted for their great crops of barley; beans, too, are cultivated with success, as well as clover and turnips. The drift soil is commonly used in the cultivation of potatoes, and preferred to any other method; and lime, though brought from a distance, is very much employed. The potatoes are extensively employed as manure. The tallow, including the butter, are accordingly in a much better condition, inasmuch as its tendency to suck the soil. The lakes impel for heating their ovens, of which a considerable amount of the best of wheaten bread is consumed in these counties.

8757. KILKENNY. 310,000 acres, mountainous, but with some rich and beautiful vales on the banks of the river, so that in winter the thermometer seldom falls below the freezing point, while in summer it ranges between seventy and seventy-five degrees. There is less humidity than in Dublin and Wicklow, as well as of the east and north winds. (Tighe's Survey of Kilkenny, 1802. Sup. Encycle Brit. Edin. Gaz. 1827.)

This county has many romantic situations, ornamented with cottage beauties, and it is not only more extensive than in most parts of Ireland, present a prospect very different from what is often met with in that country. The soil is the most part on limestone of good quality, and some parts on slate, with a fertile covering of bay bogs; for the sand declivity, about 300 feet from the northern to the south coast, is the most fertile of the whole, as water which has been in contact with the surface is carried off with sufficient rapidity to prevent its making the ground marshy. The best country in the county is that of northern boundary of the county. It is a stone coaled mixed in immense pieces, but of a subterfuge quality, which forms a very durable, and temperate, and it as, therefore, less fit for being used in families. For this reason, and the near approach of the coast, the use of the English coal is used in preference, even within a few miles of the work. The clay is several quarries of marble, chiefly of a black colour, of which a few tons are exported. Excellent sandstone and marble, and iron and lead ores, have been observed in different parts. Property in land is in several large estates, and many of a moderate extent; extreme accounts of the principal proprietors are Lords Beaufort, Clifton, and Ormond. The chief agricultural estate for the barony of Carlow is that of the netherleese. The sheep and cattle are divided among several families of the Barrow and the Wexford and Barfge, a tract of dry grass land fit for tillage, but still in its natural mode, not enclosed, and mostly. The lands of the estate were held in 1802 by one family, who kept 120 cows. The cattle are not forced much there houses, and even in the houses of the southern part of the county, curds, almost in every house, and cheese in a hundred and a half to three Irish acres. The practice of letting cows to
The common size of farms is from ten to twenty acres; and these farms are frequently held in partnerships. Large farms, however, are less rare here than in the arable tracts of the other counties, and the greater part of them are now mostly for twenty-one years and one life. Parishes and parts of parishes, as well as farms, are divided among the tenants. In some instances several tenants hold for lives renewable for ever, paying a renewal rent equal to half a year’s rent, or more, on the fall of every life. Modern leases often contain a provision against alienating. Nothing is so much complained of among the tenants as the mode in which the rents are collected.

There are several streams and two canals. A woolen manufacturer, at Clogherbridge; and a catholic seminary at Maynooth for above two hundred students.

1188

Weeds, oats, barley, and oats and barley, are the most common crops. The total value of the crops of which is not more than £100,000; of barley and oats is about thirty-two bushels per acre. Wheat, oats, barley, and oats go for four tons per acre. Herbage is well kept; and cattle, sheep, and horses are employed in lambing and spreading grass, which is sometimes drawn by only two of either; in midsummer there are two cuttings of hay; yet this and their other implements are not generally of a good construction. The threshing-machine has been introduced in this district for about twenty years.

The leases were formerly for thirty years; or, three lives; but the more common present length of lease is twenty-one years, by which the life of the tenant in possession at the end of the lease is frequently extended. The current value of the land is about £100 per annum, and the former or present tenants hold for lives renewable for ever, paying a renewal rent equal to half a year’s rent, or more, on the fall of every life. Modern leases often contain a provision against alienating. Nothing is so much complained of among the tenants as the mode in which the rents are collected.

There are several streams and two canals. A woolen manufacturer, at Clogherbridge; and a catholic seminary at Maynooth for above two hundred students.

AGRICULTURE OF CORK.

7872. EAST MEATH. 556,700 acres, of low, flat, rich surface; a clayey or loamy soil on limestone or gravel, with little wood, few mansions, and only one twelfth of bog. (Currer's Observations, 1838. Thomson's Survey of Meath, 1802. Sup. Encyc. Brit. Edin. Gaz. 1827.)

The lands of property of Meath is divided into large estates, a great part of which are divided into parcels of small holding or small land; these are for the most part let out on leases of twenty-one years, with security of tenure under the lord of the manor, in perpetuity, which have now become more valuable than the freedom of the common. Grazing was, till very lately, a more important tenant in this county than tillage. Many persons fattened cattle here on the grass, and kept large herds of sheep. These they purchase at the beginning of the grazing season, and dispose of during the summer. In many parts of the counties of Meath and Offaly it is the custom of keeping a regular stock all the year. The pastures are considered as quite in a state of improvement; and in the plains of Meath, where there is a great deal of flat ground, the grass is not carried to any extent, and the butter made here is said to be held in little estimation. In many parts of the county the landlords supply a succession of cows in milk, horses, and land, and the tenant furnishes labours, usually at the rate of one shilling per head per annum for each cow. The English long-horned cattle were introduced many years ago into this district, which now contains some of the best specimens of the breed. Some mixed breed has been also introduced, and the number of horse in the county season; and the Killeres hills, in the western angle adjoining Cavan, are remarkable for fattening sheep. The sheep are brought from other counties, and, like the cattle, the same stock is kept only for a season.

7873. WEST MEATH. 578,780 acres of surface with woods, lakes, streams, bogs, and rich grazing lands, undulating, or rising into hills of no great elevation, others covered with wood, presenting, in several parts, an agreeable scenery. (Wakefield, Edin. Gaz. 1827.)

The principal river is the Shannon; and there are a number of beautiful lakes well stocked with fish; the trout in Long Island and Lough Derg are considered as superior in quality. One of the largest of the lakes is of full wooded islands. There are few large estates, but many gentlemen of moderate fortune possess large holdings in this county, most of whom are resident. They are considered for twenty-one years or a life. Farms vary a great deal, from very small, where tillage is the principal object; but only a small proportion of the district is under the plough. It is chiefly occupied in grazing, in which the resident gentry almost exclusively employs the farms which they retain in their own hands. Some linen manufacture.

7874. LONGFORD. 294,510 acres, in great part bog, mountains, and waste; the climate on the average giving 140 dry days in the year. (Wakefield, Edin. Gaz. 1827.)

Landed property is in estates of from 2000l. to 2000l. a year. Leases are commonly for twenty-one years or a life. Farms vary a great deal, from very small, where tillage is the principal object; but only a small proportion of the district is under the plough. It is chiefly occupied in grazing, in which the resident gentry almost exclusively employs the farms which they retain in their own hands. Some linen manufacture.

7875. LOUTH. 177,326 acres, mountainous towards the north, but in other parts undulating and fertile, with little waste land, no considerable lakes, and a great number of gentlemen's seats, of which Col- lon is the chief. (Wakefield, Edin. Gaz. 1827.)

Landed property is in estates of from 1000l. to 2000l. apiece, which form a large number of small estates. There are many gentlemen of moderate fortune, who possess large holdings in this county, most of whom are resident. The principal river is the Boyne, and the great part of it is navigable. They are in a condition superior to that of the rivers in most other parts of Ireland. It is considered to require six months' time before the old ones expire, so that the tenantry is not often changed; but fines are frequently paid on these renewals, which carry away much of their value. The quality of the soil is of tolerable, not however, generally. The soil is mostly light; but in some parts it is rich and deep.

7876. WATERFORD. 434,100 acres, the greater part hilly and mountainous, but rich and productive on the south-east, the climate so mild, that cattle sometimes graze all the year round. (Wakefield, Cur- ren, &c. Sup. Encyc. Brit.)

Some very large estates, of which the most extensive belongs to the Duke of Devonshire. Leases are commonly for twenty-one years or a life; and on the banks of the rivers, where the land is most valuable, farms are small. According to Wake- field, the county of Waterford has as large an extent of fertile land as any part of the kingdom. One advantage of a farmer marries, the father, instead of giving her a portion, gives her an estate, which is commonly called a daughter's gift. If the daughter has any children, she retains the property until her death, but the property then goes to the eldest son, though the daughter gets one half of the remainder; and this division and sub-division continues as long as there are daughters to divide the property. It is the common practice among farmers to make children for the purpose of dividing the property among their offspring. Some of the dairy farmers, most of whom are in easy circumstances, pay 100l. a year rent; and a great deal of butter is made, even among the mountainous, where small cows, suited to the nature of the pastures, form the principal stock. In the neighbourhood of Waterford, cows are let for fifteen pounds, and twenty pounds, for the season.
The crops are potatoes, in favourable situations, so credited by wheat and barley; grass is also important, sometimes following the wheat. Flax is cultivated in many small plots. Hemp very rarely is grown. In the vicinity there is a great extent of tea and tobacco plantations. Sea sand, seacoal, and lime, form a useful addition to the storable and farm manures, of which the chief is manure, in more cases than one, carried away by the trade, and greatly reduced in value by careless management. Peeling and burning is practised in the vicinity, but on a very limited scale. The mode of preparation for the first crop in the country. The implements of husbandry are simple; the cows are ploughed and harrowed, seldom furnished with iron tines; drawn by horses or mules. Oranges are grown, by observation, in many houses. In general, the cattle, which are chiefly of the half Holderness breed, are

758. TIPPERARY. 887.98 acres, diversified with heaths, mountains, and fertile vales; of which the Golden Vale is among the richest land in the county. The climate so mild, that cattle grace out all the year round. There are 30,000 acres of bog in this county. From the survey made by Mr. Ather, under the direction of the commissioners for enquiring into the nature and extent of the Irish lands, it appears, that this waste land might be easily drained. (Wakefield, Sc. Surv. Eng. Brit. Edin. Gaz.)

Minerals. Slate, lead, and coal are worked. Estates are of various sizes, some of them very large, but a great number of a medium extent, worth from 8000l. to 6000l. a year. Of the proprietors, the influence of Lord L'Isle is by far the most marked. The estates have extented from 10,000l. to 15,000l. a year and upwards. The graziers here, as in Roscommon, have leased hold properties, frequently on leases to be redeemed, of which also, they often became the purchasers. Properties of this description are of very common occurrence. Tillage farming, however, is of small extent, one of every Irish acres being always under grass, or fallow, or some other crop, in many cases more than one third of the property is so cultivated. Only a small proportion of the land is in tillage; the produce of the country is chiefly corn and potatoes. Flax is also grown, and hemp, is stated by the same authority to be of a medium, that is, of a low quality. Hemp was formerly cultivated extensively on the rich low ground of the county, but the operation is now much decayed, but this tract is now occupied in grazing. Flax of an excellent quality for sail-cloth is still grown in several places. The common term of leases is thirty years and three lives. The part of the provision and corn trade is possessed by the city of Limerick.

759. CLARE. 362,520 acres, nearly half productive land, and the remainder moors, mountains, and bogs, with more than 100 lakes interspersed. The climate, though moist, is not unfavourable to health and longevity; fivers, which sometimes prevail to a great extent here, being occasionally chaly the danger of the great houses, and inhabitants to domestic and personal cleanliness. (Butler's Survey of Clare, 1808. Sup. Encyc. Brit. Edin. Gaz.)

Limestone abounds, and coal, ironstone, black marble, lead, &c., have been found, but not worked. Limestone. A few large estates, of which the most was not that belonging to the Marquess of Thomond's, leases, formerly attached to be seen.

The size of farms varies greatly. Those under tillage: from one or two acres to fifty, of the latter size there are few. Farms range from 100 to 700 acres, several of which, and sometimes in distant situations, are held by one individual. Frequently several persons join in the occupation of an arable farm, and have about ten acres each. The general term of leases from proprietors is for three lives or thirty-one years; sometimes, but not often, for three lives and thirty-one years; twenty-one years or one life, and twenty-one years and a half. The tenures of under tenants is various, and often arbitrary.

The most sufficient species of grain are cultivated with considerable success. Rape and flax, the former chiefly for its seed, and the latter for fibre, are also of a moderate extent. Potatoes occupy a part of every farm, and their culture is equal, within this county, care and judgment than that of any other species of vegetable, though at a greater expense of time and labour than would be thought necessary in most other places. In regard to the kind is both of potatoes, the greatest defect is in what are called green corn, being, with potatoes, the chief article of diet, and the most agreeable to the arable farmer; and turnips and cultivated herbage being either grown more or less, in order to some extent, or to be greater part of the county, altogether disregarded or unknown. The corn crops thus necessarily follow each other, until the soil is exhausted. As the soil is level or slightly undulating, excepting the second and sand, both of which are used as manure with good effect, cannot, or will not, admit of cultivation. Wheat and rye are also grown, sometimes for only two years without manure; in the fourth year wheat follows; and then the arable crops: they will renew the cast of soil and labour. The implements in common use are generally radically con-structed, and imperfect as well as expensive in their operation; in many parts, even where the soil is light and dry, the plough is drawn by horses already, with traces of rope, and a collar of straw. But from the roughness of the surface, the potatoes on the tenantry, and the minute division of farm land, the ground is much more extensively employed than the plough, over all the arable land of this county.

The pastures of the fens, or low grounds, on the rivers Shannon and Fergus, are equal to the fattening of the largest oxen. This rich tract extends from Parthenil to Limerick, about twenty miles, and is computed to contain about 20,000 acres of deep deep-soiled soil, over a bluish or black clay or mooraceous subsoil; producing, owing to the abundance of its occupiers, a mango with the most valuable herbage, a great quantity of rushes and other aquatic plants. The soil of this land is so great for grazing was, several years ago, as high as 52 per acre, equal to the best, and English acres, or meadows, in many instances, much more. These meadows are said to produce 120 pounds of hay or grass for every acre. The cattle of this county are almost all long-horned, good milkers, and very heavy. The dairy is almost entirely limited with Leaister rams; but there is a general complaint that the quality of the matrix wool has been deteriorated. A vast number of estates are held here, many are very generally employed by the poorer classes; but little is known of the by the present inhabitants.

Clare was formerly noted for its orchards, and for cider of a very fine quality, made from the celebrated cockspur apple, which is still found near the small town called Six Mile Bridge. Each of the counties of Clare, Limerick, and Tipperary, contain about 60,000 heads per annum, average six; and, what is very uncommon in the kingdom, the weight of the same, the latter is twenty pounds, does not appear from the latest accounts, that any considerable quantity of the exportation; but it is, this year, twenty pounds. There seems to maintain its former character, and is held in great estimation among the country people. (Manufactures are yet in their infancy. All the linen made in the county is used for home consumption.)
The mountains are chiefly occupied with young cattle and costs; sheep, apparently the most profitable animal in such situation. Most other animals are not reared, and the little cultivation to be found here is generally performed with very little labour, in small patches, where there was not a single plough.

In the low lands is clay, of different qualities; some of it seems to be a species of clay-cake, and other soils may be converted into bricks and earthenware. Excavations are not extensive, but in several places they are evident.

These islands are high enough to permit of their being held by a high head on such land as to require them to be employed; they pay their rents by the sale of butter and pigs, and by laws which their owners, the landholders, have to hire large tracts, which they stock with cows, and these cows are then let out to dairymen upon such terms as leave them a very small return for their labour.

The best corn land is about Tralee, and the low place, Bingle, where more flax is raised than in any other part of the country.

The principal crop is barley, for which Kerry alluirs for export are its raw product, beer, butter, hides, and tallow. It does not raise more corn than is enough for its home consumption, and carries on no manufacture for sale but that of coarse linen, which is on only a small scale.

Agriculture is not a large evil; and the general face of the country gives the impression of wildness and discomfort. Instead of hedgerows, mounds of cut grass stalks, called clints, are every where to be seen; and as these assert a slight protection against the wind, it is very probable that the legs of the clints are surrounded with streets of grass, and sometimes to collect together; even fewls and turkeys are thus bound.

The chief county of this part of Ireland is Leitrim, but the districts about Dunlewy and the town of Lethe, are also much inhabited.

The land is not as high as in the south of Ireland, and the soil is in many parts more sandy. The general nature of the soil is very fair, and very fertile, and is capable of being cultivated with advantage. The climate is not as warm, but is as damp, as that of the south, and the principal growth is wheat and barley, with a mixture of oats and potatoes. The grasses are very fair, and the sheep are of good quality. The county is inhabited by a firm and steady people, who are very industrious and frugal. The farmers are generally of the best class, and are capable of doing more in the way of agriculture than is generally done in the south of Ireland.

The county of Leitrim is one of the most productive in the kingdom, and is inhabited by a numerous population. The soil is very fertile, and the climate is warm and sunny, which gives a great advantage to the farmers. The crops of corn and potatoes are abundant, and the county is famous for its great stock of horses. The county is also famous for its bees, which are very fine, and the honey is much esteemed. The county is also famous for its wool, which is of a very fine quality. The county is also famous for its linen, which is of a very fine quality. The county is also famous for its flax, which is of a very fine quality. The county is also famous for its cattle, which are of a very fine quality.
The soil is generally of a light, sandy, gravelly loam, or meory; in some parts the hills are rich and fertile, but the subsoil is clay, and especially loam, unfavourable to vegetation. Numerous streams and lakes; the woods are of oak, beech, and chestnut, but not in a very strict. On the Sligo and Moville, considerable salmon fisheries; trout abound, and a white falcon on the Co. 

Near Farnham, the appearance of the country is favourable; the lakes are picturesque, and contribute much to the climate. The woods are various, but not extensive. 

Two estates are of 50,000 and 50,000 acres; besides these there are about 100,000 acres, and the land is under tillage, but the agriculture in every respect is very good. The forests are from 30,000 to 40,000 acres; but these are generally subdivided into farms of from two to twenty acres, which are held at from 6l. to 10l. per year, by tenant farmers, who pay very little rent, and may have as much as they choose to raise; their principal object is to raise a sufficient quantity of oats and potatoes, and hay, to support the people. They are very rich and fertile on the meadows, and the villages are in very good state. The chief towns are Newmarket, Enniskillen, and Lisburn, which are in a good state. 

The estates are large; three proprietors mentioned by Wakefield have about 100,000 acres each, and another three from 60,000 to 70,000. The leases are most common for twenty-one years and a life. 

In the northern part of the country, the farms are larger and more productive than in most other parts of Ireland. The hills and mountains are here not so high, and there is a greater extent of good land. The hills and mountains are here not so high, and there is a greater extent of good land. The hills and mountains are here not so high, and there is a greater extent of good land.
Book I.

AGRICULTURE OF ANTRIM.

1205

The crops are growing; and in many parts they are allowed to graze promiscuously as soon as the crop is cut. Cattle and sheep are preferred in most places. Barley is the chief grain-crop, and it is eaten both as meal and for the malt; oats are also much used for horse consumption, and wheat is confined to a few favourite spots. There are only two mill towns in the county. The culture of flax is considerable in the barony of Raphoe, and is extending even in the mountain districts. Potatoes are cultivated even in the mountain districts; and the potato is the most unknown among the tenants. Vital age or partnership farms still abound, but farms now begin to be let to individuals as separate holdings. In the low country they are ten to fifteen acres: in the mountains, 30 acres, and in the foothills of the mountains the fences are commonly nothing better than ditches, with bars of turf or clay, so that the cattle require to be herded while

Land properties.

With the exception of lands belonging to the Crown, the other parts are more subdivided into certain portions reserved by the crown to be afterwards erected into freeholds, the whole of Londonderry was granted by James I. to the twelve companies or guilds of London. The estates are, therefore, held from these companies, either in perpetuity, or on determinable leases.

The principal proprie tors or lessees are Lords Waterford and Londonderry, Conolly, Taylors, and the families of Hamilton and Powerscourt; nevertheless a considerable number of land owners are engaged in agriculture.

There are only two mill towns in the county. The culture of flax is considerable in the barony of Raphoe, and is extending even in the mountain districts. Potatoes are cultivated even in the mountain districts; and the potato is the most unknown among the tenants. Vital age or partnership farms still abound, but farms now begin to be let to individuals as separate holdings. In the low country they are ten to fifteen acres; in the mountains, 30 acres, and in the foothills of the mountains the fences are commonly nothing better than ditches, with bars of turf or clay, so that the cattle require to be herded while...

789. ARMAGH. 283,871 acres of varied and rather interesting surface of mountain, plain, and bog; with rivers, streams, and lakes, and a climate mild for the latitude; 244,000 acres are estimated fit for cultivation. A principal notice of this county is the extensive survey of it made by Captain Loughgall, near Armagh. (Coke’s Survey of Armagh, 1814. Wakefield. Sup. Ency. Brit. Edin. Gaz. 1827.)

Meadow is a very valuable quality, and of great beauty, is wrought in Ar mathe. The value is 3s. 4d. per acre, as the rewards of the commissioners of the watering in Irish.

The farms may be divided into two kinds: the first, such as are possessed by farmers who have recourse to no other branch of industry; the second, such as are held by weavers and other tradesmen. The former rent from three to five pounds in some parts of the county; the latter are here of every size, from one to twenty acres. It has been remarked that the divides the northern and southern counties, are to minute army to the east and west; and years, others for live. Lakes consist chiefly of a ditch and bank without water. The farmer has in each a very large and inferior manorial right, the face of the bank; but any old stone walls are frequent in the stony mountainous districts. It is impossible to give any accurate Idea of the number of hens and eggs are fattened; many of them breed in the county, but not a few kens of the produce of the farm, and in some parts of the county, covered with heath and other fine rocks, are well adapted to be used for the number of hens has greatly decreased during the last twenty years.

The principal manufacturer is linen. The value exceeds half a million sterling, besides brown or bleached linens.

Graeme, freeholds, and other parts of the rich rock crags, which, when cut, are termed Irish diamonds, are found in various parts. Irish, copper, lead, and coal have also been introduced.

789. DOWN. 559,995 acres, of which one eighth is mountainous and waste, the remainder hilly and productive, cultivated by small manufacturers, and not white planted. The population of the county is scattered about, and is not subject to extremes. (Dubourdieu's Survey of Down, 1802. Sup Ency. Brit. Edin. Gaz. 1827.)

Land properties.

There are some large estates, though in general it is much divided, and has all the different gradations, from the most elegant holding down to the small coast town, who farm his land. The most of it is freehold. The rental was at the average rental of the land in Scinde, as described by the commissioners of the irrigation of Ireland. The farms may be divided into two kinds: the first, such as are possessed by farmers who have recourse to no other branch of industry; the second, such as are held by weavers and other tradesmen. The former rent from three to five pounds in some parts of the county; the latter are here of every size, from one to twenty acres. It has been remarked that the divides the northern and southern counties, are to minute army to the east and west; and years, others for live. Lakes consist chiefly of a ditch and bank without water. Graeme, freeholds, and other parts of the rich rock crags, which, when cut, are termed Irish diamonds, are found in various parts. Irish, copper, lead, and coal have also been introduced.

789. ANTRIM. 622,659 acres; on the east and north mountains, destitute of plantations, and abounding in small streams, others the lower parts are level and fruitful, and the climate drier than in some other counties. (Newe's Statistical Survey. Wakefield. Dubourdieu's Survey of Antrim, 1812. Sup. Ency. Brit.)
Mistakes. Besides books, limestone, cupram, coals, sandstone, &c. are found. The fossil-wood, or wood-coal, in most places, is covered with columns of basalt, and is curious as explorers of the origin of coal. Notwithstanding the compressed state in which it is found, the bark and leaves are quite distinct, and the trees denoting the annual growth of the wood may be counted. In some instances the number of the trees may be traced. Of the two coal-mans which are wrought in the province of Mecklenburg, there is one in Antrim, at Ballyclare. The coal’s are bimammous, and the hard is a part of them are exported.

Ilanded Property. Estates are in general freehold, being either inanimate grants from the Crown, or held under those grants. The exceptions are the properties under the acts of Commonalty, and those connected with the proprietary estates of the Marquises of Hertford and the Athenian faubus. The forest of the major part of the northern forest lies in this county, which is, land capable of tillage, and independent of bog and mountain. Most of the Antrim estate is set in perpetuity, in turning with 1800, or 1803, and the annual rent and other great proprietors are the Marquises of Donegal, Lord Templeton, and Lord Brabazon of the Vale, Lord Templemore, but it is the only household under the Marquises of Donegal, who lets his land for their profit and not for tillage, but reserves the ground of a few years for a price.

The farms are in very general small. The principal feature in the tillage system is the potato fallow. The small size of the farms, and, in some places, the rockiness of the soil, precludes the use of the ordinary means of culture, and therefore a part of the land is day by day with the spade. The quantity of potato-land is regulated by the quantity of manure that can be collected. After potato, the same system, and the quantity of fallow ground is regulated by the ability to purchase the seed. A crop of oats finishes the regular rotation. When the ground is exhausted, it is too much suffering to lie till it is covered with natural grass. Such is the most general plan of husbandry pursued in the county. In those parts where the farmland is too large for the spade culture, the land is ploughed by three or four neighbours wanting their strength; one supplying the plough, and the other bringing a horse, bullock, or even a милч cow. Wheat is a plant of very modern introduction in Antrim, and very little of it is grown.

The most important crop is flax. The cultivation of flax on the mountains, belonging to small occupiers, of a small stunted breed. Sheep are very little attended to, and a few kept are of a very inferior kind. Goats are numerous in the mountainous parts of the county. Figs also are kept in great numbers.

This county by no means abounds with wood; nor are forests cultivated in great abundance, or with very much success. Of the forests which are in the county, only a few have as yet been introduced, and advantageously cultivated. All the woods of Ireland are, however, little cultivated or attended to, and it is by no means a satisfactory manufacture of cotton has, in some measure, supplanted the flax, especially in the vicinity of the coast.

There is a considerable salmon-fishing on the coast. The stupendous ascent of basalte columns, called "the Giant’s Causeway," lies on the maritime confines of Antrim.

Chap. IV.

Literature and Bibliography of Agriculture.

7896. The first book on agriculture were written by the Greeks before the Christian æra, and by the Romans about the commencement of that period. He issued is the only writer of the former people exclusively devoted to Husbandry: the earliest Roman author is Cato; and the latest, Palladius, in the fourth century A.D. The works of these and the other agricultural writers of antiquity have been already enumerated (25. and 44.), and the most interesting have lately been re-translated (7110. anno 1800).

7897. In the dark ages few books were written except on religion. The first author that appeared on the revival of the arts was Crescentius in Italy, in the fifteenth century; and soon after, in the sixteenth, Fitzherbert in England, Olivier des Seres in France, Heresbach in Germany, and Herrera in Spain. Since these works appeared, many others have been published in every country in Europe, especially in England, France, and Germany. Though our business is chiefly with the works which have appeared in Britain: yet we shall, after enumerating the chief of them, notice also what has been done in other countries; many foreign works, especially of France, Germany, and Italy, being familiar, either in the original or by translations, to the reading agriculturists of this country. All the works of importance, whether foreign or domestic, published or to be published since 1825, will be found noticed or reviewed in the Gardener’s Magazine, commenced in that year, and in continuation,

Sect. I. Bibliography of British Agriculture.

7998. A general view of the literature of British agriculture having been already given (§ 80.), we have here confined ourselves to the bibliographical enumeration of those books that are of some importance to the present day. The greater number of the works that are here referred to are of a nature not strictly belonging to this article, and being for the greater part, those on veterinary art, that have rendered much more professional, not published within the last ten years, of very little value, and a number of them more injurious than useful. This second edition of British authors on agriculture is considerably reduced, in order to enable the more easily select; and, through the obliging disposition of Mr. Forsyth, perhaps the only man in existence thorough this country, with whom the bibliography of British agriculture and gardening, is rendered much more accurate.

1550. Groschdel, Bishop of Limerick, has began a Treatise of Husbandry, which Master Groschdel, soe Bishop of Lypdon, made and translated out of Frenche into Englyshe. Lond. 1490.

1523. Fitzherbert, or Fitzherberto, Sir Anthony, a very learned lawyer, and also known as the father of English husbandry, was born at Norbury, in Derbys, and died there in 1535. He was made judge of the Common Pleas, of the Chancery of Henry VIII., and wrote several books on law.

1. The Book of Husbandry, very profitable and necessary for all men. Lond. 1523.

2. Servie ang. Lond. 1523, 4to; 1539, 8vo.

1556. Sir Thomas Elyot. Lond. 1556.

1558. Bucce, Sir Richard, Canon of Marton Ab- ter, near London. The manner of Measuring all Mover of Land. 16mo.

1569. Tussor, Thomas, styled the British Varro, was born near Warwick, in Essex, 1515; received a liberal education at Eton School, and at Trinity Hall, Cambridge; lived many years as a farmer in Suffolk, and afterwards removed to London, and published his experience in agriculture and gardening. He died in 1590.

1. A hundred good Points of Husbandry. Lond. 4to.

2. Firm Harbours Points of Husbandry, adapted to as many of Goods Harvestes; with divers approved lessons concerning fruit trees and the like. Lond. 4to.

2. A First Book of Cattle, &c. Lond. 1591. 4to.

3. A Book of Fishing with Hook and Line, and of all other Instruments thereunto belonging: a method of Salmor Engines
and Tramps to take Polcaets, Burazards, Bats, Mice, and all kinds of Vermin and Beasts whatsoever; most promi-
nent for all Warrors and Sheeres in this Kind of sports and pastime. Lond. 1699. 4to.
1651. Anon. Coppermins and the Pough. Lond. 4to.
1651. Plot, Hugh.
The most authentic and admirable Arte of Settling of Corns, with all the necessary Tools; and other Circumstances belonging to the same. Lond. 4to.
1652. Langham, Rowland.
Most approved and long experienced Water Works: contain-
ing the Design and manner of setting up a Mead, Meadow and Pasture by the Advantage of the best River, Broke, or Drain, newly discovered. Lond. 4to.
1653. Markham, Gerseas, Jarriss, or Gerris.
An author who wrote on a variety of great subjects during the reigns of James I. and Charles I., and died in 1640. He appears, says Hart, to be the first Englishman who deserves to be called a hacket writer. Lond. 1653. 4to.
2. Forewell to Husbandry. Lond. 1655. 4to.
3. Husbandry, newly improved. Lond. 1656. 4to.
4. Enrichment of the Weald of Kent. Lond. 1659. 4to.
1656. Stevens and Liehuaut.
Manning of Husbandry or Country Farm; translated into English by Richard Sarlett, Practitioner in Physick, newly reviewed, &c.; and the Husbandry of France, D.v., and Spanish husbandmen resolved and made ready to retail any here in England. By Gerrase Markham. Lond. fol.
1657. Birringer, C.
The Relation between a Lord of a Manor and the Copy-
holders, his Tenant. Lond. 4to.
1658. Plowes, Gabriel, author of some tracts on
Gardening; a poor man but a useful writer. Hart, says, he had a bold adventurous cast of mind, and partly to maintain his family, partly to vanity mediocrity. As great a genius as he was, he was allowed to drop down dead in London streets with hunger; nor had he a shirt upon his back when he published his papers to Hartlib, who seems to have published but few of them.
1. Discovery of Insects, so long hidden since the World's beginning, in the Way of Husbandry. 4to.
2. Discovery of Subterraneous Treasure, viz. all manner of Monuments and removes, from the Earth in the regions for the finding them. Lond. 1653. 4to.
3. Husbandry, newly improved. Lond. 1655. 4to.
4. Twentieth Experiments in Husbandry, with Twenty Experiments. Lond. 1655. 4to.
1659. Ferriaghe, Sir C., a native of Holland, and a colonnial Governor of New York.
Discovering the true way of setting the great Fenns lying within the several Counties of Norfolk, Suffolk, Suffolk, Cambridge, and the Isle of Ely. 4to.
1661. Wosten, Sir Richard.
Manning of Husbandry used by Brabant and Flanders, shew-
ing the wonderful improvements of Land t'ire. Lond. 4to.
1664. Elth, Walter, an officer in Cromwell's ar-
my. The fifth edition of a government holding commissaries at that time, was eminently useful in introducing improvements into Ireland and Scot-
land.
1. The English Importer, or a New Survey of Husbandry, discovering to the kingdom that some Land, both Arab's and Famine, is in the world; and the same, if well used, will ten fold. Lond. 4to.
2. Improved: improved, or the Survey of Husband-
ry surveyed. Lond. 1664. 4to. 5d Edn.
3. Hartlib, Samuel, an ingenious writer on agriculture, and author of several agricultural tracts. He was the son of a Polish merchant, and came to England, according to Wotton, about 1619; but the time when he died is not accurately known. He was a great
promoter of husbandry during the times of the com-
monwealth, and was much esteemed by all inge-
nious men in those days. Milton adds, says Hart, that William Petty inscribed two letters to him on the same subject. Cromwell allowed him a pension of 100l. a year.
1. Treatise of Husbandry, and the Discovery of the Discourse of Husbandry used in Brabant and Flanders. This work is out in the Commonwealth, and written by Robert Charles, in April 1649, Lond. 4to.
2. Appendix to the Legacy, relating more particularly to the Husbandman and Natural History of Ireland. Lond. 1654. 2d Edn.
3. Essay on the Advancement of Husbandry and Learning, with a proposall for erecting a College for the benefit of that art. Lond. 1654. 4to.
4. Improved Husbandman; or, a brief Treatise on the Errors, Infections, and Inconvenience of our English Husbandry, in planting and sowing for Corn; with some necessary and charitable Observations to be observed for the benefit of that which will join in this good and public work. Lond. 1654. 4to.
5. Design for Plants, by a Universal Planting of Trees; ten-
dred, or the number of trees, necessary to be planted with the Publicke. Lond. 1655. 4to.
6. Design for Division or Setting out of Land in England and Ireland. Lond. 1655. 4to.
7. Improved Husbandman; or, a Discourse of Hus-
bandry, both Foreign and Domestic. And a particular discourse of the Natural History of Husbandry. Lond. 1659. 4to.
1668. Speed, Adam.
1. Adam out of Eden; or, An Abstract of divers excellent Experiments, touching the Advancement of Husbandry. Lond. 1660.
1662. Digges, William.
History of the embanking and draining of divers Fens and Marshes, both in former parts and in this Kingdom. Lond. fol. 3d edit. pi. 1671. 4to.
1663. Foster, John.
England's Haplograce increased; or a true and easy Method against all such edging dyes, by a Plantation of the Roots called Potashes, &c. Lond. 1654.
The Design for the perfect Draining of the great Level of the Fen, called Reeds, &c. Lond. 1665. 4to.
1669. Wodehouse, John, gentleman, author of some
works on gardening.
2. Smith, John, Gent.
England's improvement revived; plainly discovering the se-
veral Wavs of improving the land; the works of the Latter
Grounds, and of enriching all Earths; with the natural Quality of the various Land, and an exact Map of the Fens, which is
therein, observed; together with the manner of planting all Sorts of Timber, and Undertown; &c. collected in 30 Years' Practice: in 6 Books. Lond. 1655.
1670. Houghton, John, F.R.S.
A Collection of most curious Improvements of Husbandry and Trade. Lond. 4to. Again in 1728. 4 vols. svo. revised, by J. Broderby.
1673. Lister, Martin, M.D., an eminent physician and
natural philosopher; was born in Buckingham-
shire about 1648; practised in London; died 1711. 12.
1674. Toole, W.
A Catalogue of Plants which may be usefuly cultivated for Grass or Hay. Lond. 1674. 4to.
1675. Moore, Sir Jonas, Knight, F.R.S., a very
respectable mathematician, and surveyor-general of his
majesty's ordinance, was born in Lancashire, 1675; died 1757.
1. History or Narrative of the great Level of the Fens
called Bedford Level; a large part of said Level, so divided, surveyed, and described. Lond. 1675. 12mo.
1678. Floyd, Edward.
The Account of Locusts in Wales. (Phil. Trans. Abr. ii.
p. 617.)
2. On the spontaneous Combination of several Hay-stacks, &c. (Phil. Trans. iv.
p. 436.)
1679. Donaldson, James, a native of Scotland, and
one of the first Scotch ingenious writers on
the agriculture of his country.
Husbandman, Anattempted; or an Enquiry into the present
state of Tilling and Managing the Ground in Scotland, Edin. 12mo. 1691.
1681. Manger, Leonard, author of The English
Gardener and other Works.
The Mystery of Husbandry. Lond. 12mo.
1690. Neurs, Timothy,
Cambridge Faculty; or a Discourse of the Benefits and
Improvements of Husbandry. Lond. 4to.
1697. Mortimer, Alexander, author of some tracts on
religious education. His works on husbandry were
translated into Swedish, and published in Stock-
holm, in 1727.
1. The whole Art of Husbandry, in the way of Managing
and Improving Land. Lond. svo.
1677. Loudon, E., brother to John Laurie, a clergyman, author of a gardening work.
(See A.D. 1735.)
The Duty of a Servant to his Lord; with an Appendix on Farning. Lond. 1677. 4to.
17.1. Bradly, Richard, F.R.S., and Professor of Botany in the University of Cambridge; a most
voluntary writer on gardening, botany, &c.; died 1732.
1. Philosophical Treatise of Husbandry and Gardening. Lond. 4to.
3. Experimental Husbandman and Gardener, Translated from the German. Lond. 1726. 4to.
5. The Week's Divertisment, an Essay on Husband-
ry, Arts, and Sciences. 21 Nov. 1727. svo.
6. The Reverend Mr. of Newington, translated from the Greek. Lond. 1727. svo.
7. The Riches of a Hope Gardener, compiled from the ob-
servations on the most celebrated Hope Planters in Britain. Lond. 4to.
17.2. Adm.
7. The New System of Agriculture; being a complete Body of Husbandry and Gardening in all the parts of the
Land. Svo.
17.3. Mackintosh, Robert.
17.4. Richards, John.
The Gentlemans and Tawsons of Masons instructed. Lond. svo.
at Bloxholme in Lincolnshire, and author of a meritorious work on fruit trees.
1740. 

Fisher, J. M., for the Improvement of dry and barren Lands. Lond. 1760.

1741. 

Mordant, John. 

The Husbandman, or the Duty of a Servant to his Lord. Lond. 4 toms. 1760.

1742. 

Adam, A., Minister of Dunse in Scotland considered a good classical scholar, and an excellent practical farmer. He died before The Husbandman of the Ancients was prepared for the press, in the occasion of some defects in that work.

1743. 

Trelawny on Agriculture. Edin. 5 toms. 1762. This is one of the best works on tillage that ever has appeared.

1744. 

The Husbandman of the Ancients. Edin. 2 toms. 1762. 

1745. 

Museum Rassieum et Commerciale; or Select Papers on Agriculture, Commerce, &c. Lond. 6 toms. 1767.

1746. 

Leicester, or Yorkshire. Lond. 1768.

The Farmer’s New Guide. Lond. 1769.

1747. 

The Semi-Virginial Husbandry, derived from various Enemies. Lond. 1767.

1748. 

Construction and extensive Use of a new-invented Seed Farrowing Flagon, suited to all sorts of a Draining Flagon; and of a Potato Drill Machine; with the Theory of a Common Plough; illustrated with 7 plates. Lond. 1764. 4 toms.

1749. 

Fodger, George, M.D., F.R.S, a distinguished physician, and teacher of medicine in London; was born at Aberdeen, 1756; died 1762. Elements of Natural and Medical Botany, containing the Specie Names of Plants; and the Rise of the Science of Botany. Lond. 1766.

Homer, Henry, an excellent classical scholar, was born in Warwickshire, 1762; died 1791.

1750. 

The Nature and Method of discovering the Specie Names of Proprietors upon the Inclusion of Common Titles. Lond. 1767.

1751. 

An inquiry into the Means of Preserving and Improving the Publick Foods of this Kingdom. Lond. 1767.

1752. 

The Complete Farmer; or a General Dictionary of Husbandry in all its branches, newly and wholly revised, and entirely corrected. London: 1767.

1753. 

Young, Arthur, F.R.S, a eminent agriculturist, secretary to the Board of Agriculture, was the son of an eminent physician in London, and author of An Historical Dissertation of Corruptions in Religion. He was born in 1741. He served his apprenticeship to a wine merchant; but on entering into the possession of his paternal estate, near Bury St. Edmunds, he became a farmer, and impoverished himself by experiments. After this he set up as a teacher of others; and in 1771 published a volume called The Farmer’s Calendar, which was followed in 1783 by The Annals of Agriculture, in which he had Ralph Robinson, George H. I.'s farmer, and other correspondents, who made excursions through the British islands and on the Continent, to collect information on subjects of rural life. At length a Board of Agriculture was established, of which he was appointed secretary, with a salary of six hundred a year. He became blind some years before his death, which happened February 1790. His works are numerous, and his travels amusing. (Annual Biography).

2. The Farmer’s Letters to the Landlords of Great Britain. Lond. 1770.

3. A Six Weeks’ Tour through the Southern Counties of England and Wales. Lond. 1770. 2 toms.

7. Rural Economy; or Essays on the Practical Part of Husbandry. Lond. 1771.

8. A Course of Experimental Agriculture. Lond. 1770.

14. Views of the United States 1782,3 (and 9). More information in particular with a View of averting the Cultivators, in the Western States, from the Improper Proposals of Foreign Men of Business, 1782. 4 toms. 1779.

15. General View of the Agriculture of the County of Suffolk; drawn up for the Board of Agriculture of the Kingdom of France. Bu! St. Edmunds, 1792. 4 toms. 1792.

16. General View of the Agriculture of the County of Lincoln; drawn up for the Board of Agriculture. Lond. 1799.
1760. Home, Henry, usually called Lord Kames, an eminent Scotch lawyer, philosopher, and critic, was born at Blair Drummond, near Stirling, where he was educated; and in 1755 died. He farmed his own estate in Berwickshire many years; he afterwards removed to Blair Drummond, near Stirling, where he made various and extensive improvements in the most curious part of which was the clearing, cultivating, and populating his hundred acres of land. He was a great cultivator of his own estate in Gloustershire. 

1777—1816. Anon. Letters and Papers on Agriculture, Planting, &c., selected from the Correspondence of the Thirteenth and Fourteenth of the 10th of July and 12th of August, 1777. London, 1816. 8 vols. 4to.

1775. Anderson, James, LL.D., an eminent agricultural writer, was born at Hermiton, a village near Edinburgh, and was educated on a farm managed by his parents; which had possessed for several generations, and which he was intended to inherit and cultivate. He lost his parents at an early age, but his education was very well regulated; and he was sent to Edinburgh, to study law, at the age of fifteen. He died in 1784, at the age of thirty-five.

1777. Harrison, Gustaveus, Esq. Agriculture Delineated; or, the Farmer's Complete Guide, being a Compend of the System of Agriculture now practiced in the University of St. Andrews.

1778. Anderson, James, LL.D., an eminent agricultural writer, was born at Hermiton, a village near Edinburgh. He was educated on a farm managed by his parents, which had possessed for several generations, and which he was intended to inherit and cultivate. He lost his parents at an early age, but his education was very well regulated; and he was sent to Edinburgh, to study law, at the age of fifteen. He died in 1784, at the age of thirty-five.

1785. Marshall, William, Esq., a native of Yorkshire, brought up to trade, but he was afterwards in the West Indies, as a planter; returned about 1775, and took a farm in Surrey; went down into Norfolk as agent to Sir Harford Harford's estate in 1780; and left this situation in 1784, and went and resided at Stafford, near the junction of the four counties of Warwick, Stafford, Stafford, and Derby, where he remained till 1790, occupied in collecting materials for his Economicus, and in printing some of his works. From this time till about 1818, he resided chiefly at Clement's Inn, London, in winter, and visited different parts of the country during summer. He spent one summer in Perthshire, chiefly on the Earl of Breadalbane's estate at Taymouth; and partly also on the Earl of Mansfield's at Scoto. He proposed arrangements for the tenantable land, and also the park and woody scenery on various estates; and finally retired to a considerable property he purchased in his native country, in the vale of Cleveland, in 1808, where he died at an advanced age in 1816. He was a man of little education, but of a strong and steady mind, and his works, in the most consistent manner, from the year 1780 to his death, the plan he originally laid down; that is, the system of collecting and publishing the practical result of agricultural practices of the different counties in England, with a view to a general work on Landed Property, which he published; another on Agriculture, which he published in 1809; and his other works on Agriculture and Landed Property, which he published in 1810, and the next year, in the Monthly Review, by which he was supplant by the Board of Agriculture.

1. Minutes of Agriculture, made on a Farm of 500 acres, of various Branches, by Sir Edward C major. London. 1763. 4to.

2. Experiments and Observations concerning Agriculture and the Weather. London. 1779. 4to.

3. The Rural Economy of Norfolk. Lond. 1788. 2 vols. 4to.

10. The Experienced Farmer, Lond. 2 vols. 1801.

11. A Tour in America, in 1784, 1785, and 1786, exhibiting a particular Account of the American System of Agriculture, with its recent Improvements, in 1805. Lond. 1787.

15. Brown, Robert, Esq., formerly farmer at Markle, near Haddington, one of the projectors, and for many years editor, of the Farmer's Magazine (see 1794.) a man of vigorous intellect, sound knowledge in political economy, energetic language, and an excellent head and wheat farmer.

20. Somervile, Right Hon. John, Lord. He died at Veyay in Switzerland, on his way to Italy, about 1791, was buried in the city of Paris and afterwards disinterred and brought to England.

21. Address to the Board of Agriculture on the Subject of Sheep and Wool. Lond. 1806.

22. The System followed during the Two last Years by the Board of Agriculture, to the Encouragement of Sheep Rearing. Lond. 1805.

27. Stacey, Rev. Henry Peter, LL.B., F.L.S. (On ornamental Sheep and Turnip Crops. Lond. 1808.)

28. Parry, Caleb Hitter, M.D., F.R.S., physician, Bath. He cultivated his own estate, and greatly improved the Merino rans, a breed of sheep

29. Howatt, General. Gen. George, first president of the United States of America, and commander in chief of the armies, was born in the Lind. 1732; 1792; 1806. A most illustrious character of the age in which he lived; his mantle seems to have fallen on General Lafayette.

30. Letters from a Traveller in Sicily to Sir John Sinclair, on Agricultural and other interesting Topics: encraved from the original Letters, as the exact Fac-simile of the Plates that celebrated Character. Lond. 1806.

31. Lettres a M. le Prince de Caramanian, containing a Account of his Husbandry and Agriculture. Lond. 1801.

34. Parry, Caleb Hitter, M.D., F.R.S., physician, Bath. He cultivated his own estate, and greatly improved the Merino rans, a breed of sheep

35. Howatt, General. Gen. George, first president of the United States of America, and commander in chief of the armies, was born in the Lind. 1732; 1792; 1806. A most illustrious character of the age in which he lived; his mantle seems to have fallen on General Lafayette.

36. Letters from a Traveller in Sicily to Sir John Sinclair, on Agricultural and other interesting Topics: encraved from the original Letters, as the exact Fac-simile of the Plates that celebrated Character. Lond. 1806.

37. Lettres a M. le Prince de Caramanian, containing a Account of his Husbandry and Agriculture. Lond. 1801.

1892. Bell, Benjamin, F.R.S.E., surgeon, Edinburgh.

1892. Laudator, Rev. Charles, minister of the parish of Newlands, in the County of Peebles; a man of sound views of political economy, whose works, and whose communications to the Farmer's Magazine, have greatly enlightened the farmers in Scotland. He has subjects of rent, demand and supply, market prices, value, &c.

Grannia Hammock, or Representations of the British Brasses; with Remarks and occasional Descriptions. Lond. 4to.

1894. Dickson, R. W., M.D., of Hadnoll, Middlesex, author of various works. He died in London, in various circumstances, in 1894.

1. Practical Agriculture. Plate.

3. The Farmer's Companion; being a complete System of Mid-Dern Husbandry. (Being Practical Agriculture, with a new title-page.) Lond. 1811.

1. Luctock, John, woodstiller at Leeds.

The Nature and Properties of Wool illustrated; with a Description of the principal English and Foreign Kinds. Lond. 4vo.

2. A Book on Wool, containing an Examination of the nature and properties of wool in every part of the Kingdom, and the Means pointed out for its Improvement. 1807.

3. Pearson, George, M.D., F.R.S., senior physician to St. George's Hospital, lecturer in chemistry, and on the theory and practice of medicine in London.

A Communication to the Board of Agriculture, on the Use of General Vaccination, or Phylepharyngeal Inoculation; and on the Facility of Paring and Burning depending partly on Oxide of Iron. Lond. 1805.

4. Sowercliffe, Robert, a surgeon in Haddington, and for some time joint editor with Brown of Marble of "The Farmer's Magazine." (See 1795.)

He died in 1805.

General View of the Agriculture of East Lothian, from the paper of the late Ed. Somerville. Lond. 8vo.

1807. Aiton, William, Esq., sheriff-substitute for the middle ward of Lanarkshire, author of various papers in "The Farmer's Magazine."

The Cultivation and Cultivation of Moss, &c. Glasg. 1807.

2. General View of the Agriculture of the County of Ayr, with observations on the Means of its Improvement. Glasg. 1808.

5. Barber, William, a London architect.

On Productions of the Vale of Wakefield; including Designs for a Cottage, Farmhouse, Lodges, Farm-yard, &c. 8vo. Passages and Description of the Mode of Building in Pass. 1806. 4to.

A Treatise on Gypsy Land; on its various Uses, and on its Application as a Marambe. Svo.

1. Main, James, land surveyor to the Prince of Wales, &c.

A Compendium of Modern Husbandry, &c. Lond. 3 vols. 1807.

1808. Smith, William, engineer and mineralogist; a man of extraordinary exertion and merit, more especially, having been the first to compose a geological map of England, and also most valuable county geological maps.

1. Improvement of H essayed Land by Irrigation, as carried into effect by Mr. Smith. Lond. Svo.

2. Woodlands, on the Hill, Form, and Management of Water Meadows, and the Draining and Irrigating Peat-lands; and other extraordinary Improvements conducted for the Improvement of Land. Lond. 1805. 8vo.

4. An Abstract of the Table of British organised Fossils. 1819. 4to.

1808. Munrow, John, a land surveyor at Edinburgh.

1. Tables for computing the Weight of Hay, Cattle, &c. by Measurement. 1808.

2. Farmer's Pocket Companion. Edin. 1812. 8vo.

1809. Vancouver, Charles, land valuer.

A General View of the Agriculture of the County of Devon. Lond. 8vo.

1809. Survey of the Agriculture of Hampshire, including the Isle of Wight. 1811. Svo.

1807. Holland, Henry, Esq., M.D., honorary member of the Geological Society, author of Travels in Greece, and other works; an eminent London physician.

General View of the Agriculture of Cheshire. Lond. 1807. 8vo.

1808. Cowley, Andrew, M.D., professor of agriculture in the university of Edinburgh; a learned, ingenious and benevolent man. He cultivated his own estate in Kinross-shire, and was extensively employed as a land valuer and rural counsellor. He died in December 1820.

1808. Gray, Andrew, a retired machinist at Edinburgh.

Plough-weight's Assistant; or, a Practical Treatise on various Implements employed in Agriculture; illustrated with 16 Engravings in the Text. Lond. 1808.

1808. Reddick, Thomas, M.D., born in Shropshire, was lecturer in Botan, at Oxford, and afterwards was a lecturer in the Museum, where he died, 1816.

1. Good Advice for the Husbandman in Harvest, and for all those in the various Branches of Agriculture. Lond. 1809. 1 8mo. &c.

2. For others who will take it in warm Weather. Lond. 1809.

4. An Improved System of the Culture of Grass, and of the various Methods of its Cultivation, which vary little at Low Temperatures. (N. and J. J. 1810)

1809. Carven, John Christian, M.P., of Workington Hall, Cumberland.

2. A Tour in Ireland. Lond. 1816. 8vo.

1809. Stevenson, W., Esq., M.A., librarian to the Treasury, author of various works, and a writer in the principal encyclopedias. He died in 1893.

General View of the Agriculture of the County of Surrey. Lond. Svo.

1809. Williamson, Capt. Thomas, upwards of 20 years in the India Company.

Agricultural Mechanism; or, a Display of the several Properties and Powers of the Vehicles, Implements, and Machinery connected with Husbandry. Lond. 1809. 12mo.

1810. Davies, Walter, A.M.

A General View of the Agriculture and Domestic Economy of North Wales. Lond. 1810. 8vo.

1810. Adams, George.

1810. Farish, John, Dumfries.

A Treatise on the Growth of Trees. Lond. 1810.

1811. Keith, George Skene, D.D.

A General View of the Agriculture of Aberdeenshire. Lond. 8vo.

1811. Henderson, Robert, farmer at Broomhill, near Aberlour, in Morayshire.

1811. Farley, John, mineral surveyor. A man of sound views on all subjects; a philosopher and an individualist, and territorial improver of great experience.

General View of the Agriculture and Mines of Derbyshire. Lond. 1811. 8vo.

1811. London, John Claudius, F.L.G. Z. and H.S., landscape gardener, author of the Encyclopaedia of Gardening, and other works, and founder and con-
An Essay on the Use of Salt for Agricultural Purposes, with Instructions for its Employment as a Manure, and in the Feeding of Cattle, etc. New Edition in 1827.

1820. On the Conversion of arable Land into Pasture, and on other rural Subjects. Lond. 1819. 12mo.

1820. The Management of Farm-yard Manure, and on other rural Subjects. Lond. 1819. 12mo.

1821. Rigby, Edward, M.D. F.L.S.

1821. On the Conversion of arable Land into Pasture, and on other rural Subjects. Lond. 1819. 12mo.

1821. A Treatise on the Management of Hedge and Hedges. 4to.

1822. On the Economy of Farm-yard Manure, &c. 12mo.

1822. On the Culture of Wheat. 12mo. 1821.

1823. On the Growth of Wheat. 12mo.

1823. Rigby, Edward, M.D. F.L.S.

1823. On the Conversion of arable Land into Pasture, and on other rural Subjects. Lond. 1819. 12mo.

1823. Holtham, its Agriculture, &c. 12mo.

1823. On the Conversion of arable Land into Pasture, and on other rural Subjects. Lond. 1819. 12mo.

1823. The Management of Farm-yard Manure, &c. 12mo.

1823. The Art of valuing Rents and Tillage, and the Tenants Right on estatements contained in an Account of the National Produce and Bank of England.

1823. Buchanan, George, civil engineer.

1823. Cleghorn, James, accountant in Edinburgh, and conductor of the Public Ledger. A Printer's Thoughts on the Establishment of a General Provident Institution for the Benefit of the Working Classes, &c. 4to.

1825. Withers, William, junior, Esq. of Holt, Norfolk.

1827. Waistem, Charles, Esq., chairman of the
Committee of Agriculture, of the Society of Arts.

Edited by Joseph Jeming, architect, member of the Institution of Civil Engineers, inventor of the Sep- tember and October, author of the August and September, editor of the following works, and some continuations, in addition to the following:

1.上半年
2. 秋季
3. 季报
4. 年报
5. 月刊
6. 季刊

By simple conti- nuous motion, instruments for drawing Curves, &c.

Bestor on Agricultural Buildings, &c., &c., to which are added, Plans and Remarks on Cattle Barn and Other Rural Buildings, by simple continuing motion, for drawing Curves, &c.

To partake of the benefits of scientific agriculture, and to promote the introduction of the most approved systems of farming, the following works have been selected for the use of farmers:

2. Teniers’ Advice to his Neighbours, on the Use and Abuse of Soil and Manure, &c. Exeter, pamph. 8vo. 1831.

The Price Essays and Transactions of the Highland Society of Scotland are published along with this work. See 1799. 1823. Kennedy, Lewis, Esq., son of the late Rev. William Kennedy the first of the present series of the magazine, was the second surviving son of the late Rev. William Kennedy, afterward Lord Willoughby De Eresby, author of the Tenantry of Land in Great Britain, &c. 1823-1831. In the lists of the different Society of the Arts, the work is not recorded; and therefore difficult to give the dates of the operations undertaken by the Society, as well as the numbers of its members. 2. The present State of the Tenantry of Land in Great Bri- tain. See the preceding list of works, and the corresponding sections of the Annual and quarterly numbers of the Monthly Journal. 1823. Lambert, Joseph, Esq. Observations on the Rural Affairs of Ireland, or a Practical Treatise on Farming, Planting, and Gardening, adapted to the Circumstances, Resources, Soil, and Climate of the Country. Dublin, 8vo, pp. 347.

James, Stephens, George, drainer, member of the Nerican and Wernick Agricultural Societies in Sweden. The Practical Irrigator; being an Account of the Utility, Formation, and Management of Irrigated Meadows, with a particular Account of the Success of irrigation in Scotland. To which is added, a Practical Treatise on straightening water-courses, protecting River Banks, and embanking Low Lands. Edin. 8vo. 1828.

1829. Sisters, Oliver de, the Lord of Predis in Laugisseac. He was born in 1590, and died in 1679, at the age of 80 years. He was employed by Hen- ry IV. to form a plantation of the white mulberry in the department of the Tarn, and was generally considered as the father of the culture of that tree in France. He published a great many useful works, the principal of which is his Théâtre d’Agriculture, published at Lyons in 1673, and the edition of which was published in 1691, and the 20th in 1675.

The Théâtre d’Agriculture and Mesange de Champs, Paris, small 8vo, was originated in 2 vols. 8vo, with a volun- tary Notes, and a Historical Introduction, 1691. 1830. Eic, a learned professor at Bour- deaux, author of a work on land surveying. La Maision Champestre. Paris, in 8vo.

Sect. II. Bibliography of Agriculture in Foreign Countries.

Numerous works on agriculture are published in the French and German languages, and a consid- erable number in the Italian; but a great proportion of these are translations from British authors. Very few agricultural books have been printed in the Dutch, Flemish, Danish, Swedish, Polish, Spanish or Portuguese languages, and several of these are translations from French, and are mostly the editor’s opinion, and a few American books.

Of French books on agriculture we have given a selection only; those who wish to see a complete list are referred to the Bibliographie Agronomique, Paris, 8vo, in which are given the titles of upwards of 2000 works, including translations and books on gardening. A general idea of French culture in all its branches may be obtained from the Nouveau Cours Complet d’Agriculture, 16 vols. 8vo (edition of 1821), compiled by the members of the Section of Agriculture of the French Institute, each of whose names are given to the articles he contributed.

1529. Etienne, Charles, et J. Lébault, physicians. Étienne, i.e. Stephano de Stephano, in the beginning of the sixteenth century published various small tracts on Gardening and other rural topics; and in 1529 he published together and published them under the title of Præsidium Rusticum, treating of gardens, trees, vines, fields, meadows, lakes, forests, orchards, &c. Having married his daughter to Liébault, the latter afterwards studied agriculture com- pletely, and published the Maison Rustique, the modern editions of which are still the most popular agricultural works in France.

1. Præsidium Rusticum; in fol.
3. Heydenon, Philibert, a lawyer both at Châlons and Dijon, in 1695.
1653. Pinot, Charles, son of a physician of that name.

1703. Liger, Louis, born 1658, died in 1717. In the later years of his life he seems to have been a bookseller, or an author by profession.

1. Dictionnaire des Terres propres à l'Agriculture, avec des Instructions et Exemples.

2. La Nouvelle Maison rustique, ou Economie Générale des Habitants de la Ville de Paris.

3. L'Economie Générale de la Campagne, ou Nouveau Mâs-

son rustique.

4. Art et pratique de l'Agriculture. 3 vols. in 8vo.

5. De l'Insecte et de l'Industrie. 1703.

6. Traité de la Chasse, de la Pêche, et de la manufacture des Poissons.

7. Discours sur la prudence et l'agriculture des plus avantageuses à la Province de Normandie.

9. L'Agronomie, ou Compend. des Principes de l'Agricul-

ture, 8 vols. in 4to.

12. Préambule contre l'Agronomie, or l'agriculture réfute ses erreurs.

16. Lafitte, Clement, advocate, and member of several societies.

17. Memoire sur les Moeurs de plusieurs gens dans le pays d'Ancenis, in 1765.

18. Essai sur l'influence naturelle de la Taupe. Sur les diffé-

rents moyens qu'on peut employer pour l'éloigner. La Rochelle, in 8vo, 1766.

19. L'Etat de la faible, Simeon Philibert de, of Rheims.

20. Des Pratinaires, in Moeurs de perfectionner l'Agricul-
	ure dans toutes les Provinces de France, surtout en Champagne, par le bon usage des plantes nuisibles avec un Traité sur la Culture de la Taupe, et des Insectes, in 1764.

22. Memoire sur la Garenc and the Culture, in 1790.

24. Des Plantes, in 1764.

26. De la Nouvelle de la Culture des Chaumes, in 1764.

27. Dictionnaire d'Agriculture, 2 vols. in 8vo.

28. Blanchet, librarian to the King of Conti.

30. Talley, of Bourbon, a zealous agriculturalist, author of several works.

31. Died in 1797.

32. Dissertation sur la Cueillette, or about the Grains of rice in the Abyssinian.

33. Huet, E. H.

34. Instruction on the manner of cultivating and perfectioning the Bees.

35. Aizet, Pons Augustin, an advocate, and in-

delicate compiler.

37. Echon, Joseph, a physician, and member of several societies.

38. Died in great distress at Paris in 1787.

39. Wrote above three hundred volumes relative to medicine, agriculture, the veterinary, and artificers, and a treatise on the science of cultivated plants.

40. Died in 1741.

41. Hérault.

42. Letter on the mode of injurious and conserving the Culture of Vegetables, in 8vo.

43. Letter on the Use of Sennu in 1783.

44. History of the Insects about the Animal, and in the Arts.

45. In 1783.

46. Manuel social and economic of the Plants, containing their Provisions for the Insects economic.

47. Paris, in 1792.

48. Huet, E. H.

49. History of the Insects about the Animal, and in the Arts.

50. In 1783.

51. Experiments on the Fossoins to the Empire of the Monarch, preceded by the Histoire Naturelle of these Animals, in the Art.

52. Dissertation on the Bettering and the Pêche de l'Empire, their Culture, and the History of the Fish.

53. In 8vo.

54. Dissertation on the Fish, in 1790.

57. Dissertation on the Mississippi, in 1790.

58. Letter on the Difference which is found between the Grande and the Petite Culture, 1790. in 1791.

59. Journal d'Agriculture, &c. in 8vo.

60. Dussart, Louis, formerly a member of the constituent assembly.

61. Letter on the difference which is found between the Grande and the Petite Culture.

62. Journal d'Agriculture, &c. in 8vo.

63. Chénard, Louis, Marquis de, an amateur apple grower and cicerier.

64. De l'Eau relatively to the Economy of the Agriculture, or the Treatise of the Irrigation of the Plains, in 1790.

65. Dussart.

66. De l'Eau relatively to the Economy of the Agriculture, or the Treatise of the Irrigation of the Plains, in 1790.

67. Journal d'Agriculture, &c. in 8vo.

68. Chénard, Louis, Marquis de, an amateur apple grower and cicerier.

69. Of the Agriculture, &c. in 8vo.

70. Dussart.

71. Lesbaras, Louis, of Marseilles.

72. Trousseau, Louis, Jean Henri.

73. Originals and Observations on diverses Arts d'Agriculture.

74. Sen. 8vo.
1769. Champollion, a clergyman.

Maun, a Member of the Assembly, and advocate at Vienne in Dauphiny.

The Cenotaph in the Campagne, whichRéponse to the Question: questions about the method and purpose of the Cenotaph of the 17th century and its influence on culture and society.

1770. L'Heure, a friar, in Dauphine.

Message to the Crown about the state of the Chevrons that he does not wish to accept.

2. Réglage de l'Heure, of Cretz, in Dauphine.

Mémoire sur la Culture de l'Epinette, or, Sanitary. 1186.

1771. Sécurité.

7. Mémoires sur diverses Constructions dans le Terroir et Argois, and on the useful parts of the Mensuration des Couverts. Fossé, 1914.

1772. Jésuite, a missionary at the Péniche.

Réflexions sur l'agriculture, and on the consequences of the policy of the vile of Moidrey in Environns. Poem commemorating the death of Rieu-Lon, Envoyer de la Côte de l'Indus, and of the Mare des Indes, mourant en 1774. Paris, 5 vols. Seulement c'est un ouvrage de plus un rapport.

1773. Foi, an eminent French chem- ister, in 1727; 5 vols.; 1773.

1774. Bossi, François, born in Lyons, 1734, and killed there on the 29th September 1783, during the siege of that city, by a bombshell, which buried his body.

Le mouvement est surtout au profit de l'agriculture, and on the ruins of the apartment where the Ache had died, he began his career as an author, by writing in the Journal of Physique et de l'Histoire Naturelle, of which Gauthier Dagoty was editor. He himself devoted himself to his agricultural work by which he is chiefly known. He cultivated a farm near Beziers, which was for Young removed to see when he was 17 years old in France in 1787; but the Ache had left it on account of the Bishop of Beziers, who kept a museum somewhere near, and for his more commodious purposes, and. The Ache, like other men who depait from common practices, was looked on as a fanciful and wild cultivator; and, because he put his tables and his works, it was accused of his being a naturalist and a neighbor that he paved his vineyard. He wrote a great many works, chiefly on agriculture.

1. La Reforme, with an extra Journal d'Observations sur la Physique, in 1790.

1775. Recon, Gabriel Leopold Charles Am. a French miscellaneous writer, was born at Remen- nev, and died in Paris in 1778; a great turn for Natural History, and assisted Boulain in the latter volumes of his great work.

2. Guichâne d'Agriculture, or Bibliographie des Gens de la Campagne, 1773. Élém.

4. Encyclopédie, a friar of the order of Citeaux, in the abbey of Trisay.

Principes de Cultivateur, ou Poste sur la Culture des Champs, and on the艺术 which can be used to solve the Maladies of the Cultivators, des Leve, and des Rompe for the genius. 2 vols. in 16mo.

1776. Ancevitch, Hubert Paquent, a librarian in Paris, was born on the legions of the age of Louis XVI.

3. De l'Etablissement Rural de Rambleuil. et principalement celui de la Basse Loire et de la Loire qui en a eu le 28 prairies, an x. 4vo. 1803.
7. Gilbert, François Hilaire, born at Châtellerault, died in 1757, and at St. Aval in 1800, in 1760, when in search of a flock of merinos; a man of great zeal for agriculture.
9. Barbe-Marbois, of Mtes, who filled various civil offices, and was a grand officer of the Legion of Honor.
11. La Richesse des Cultivateurs; ou, Dialogue entre Benja-
13. Lattre, Charles Philippe de, member of various literary, philosophical, and agricultural societies, an active patriot, and zealous philanthropist.

German Works on Agriculture

1784. Chabot De l'Evêque, Comte de, councillor of state, and protector of the Peace.

Subsect. II. Bibliography of German Agriculture

7901. The German agricultural works are as numerous as those of the French, but chiefly translations, and these, for the most part, from the English. We have given a very limited selection, the German language being less generally understood than either the French or Italian. In forest management (Forst- wesen), the English language is rich and is chiefly translated; and descriptions of English lands, and the English farmers, practices, which can be of any interest to the British cultivator. The older German works in rural affairs are enumerated in Haller's Bibliography; and the modern ones, and new editions in Ersch's Handbuch der gesammten Literatur, and in the Leipziger Catalogue, the highest in repuat as an author, and Sickler's Deutsche Landwirtschaft, a voluminous work, will give a general idea of every part of German husbandry.

1758. Herrnschau, Conradus, counsellor to the Duke of Cleve; was born in 1738, died in 1758. He wrote a number of theological works, besides his Rei Rastitae, Libri IV, which was published in 1750, and his Legum rusticarum et operarum per singulas conditorias institutae, in 1752. The former was translated by Barnaby Googe, of Lincolnshire, with the following title.

1758. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1758. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1759. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1759. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1759. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1759. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1759. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1759. Honegger, Friedrich, containing the whole Art and Trade of Husbandry, Gardening, Graving, and Planting, with the Description and Commentation thereof. Newly Englished and improved by Barnaby Googe. (Esquires.) At London, 1758. Leaves 134, besides the Dedication, Epistle and Table at the end. A very fine English Copy, with the English Plants exhibited in consisting Lands, at the end.

1800. Thauer, A., of the establishment of Mögenlin in Prussia, one of the most enlightened German agriculturists, author of numerous works, all in high repute. He died at 79, an advanced age, and deeply regretted by all who had the happiness of being his pupils, in 1829.

1800. Huber, F., of Laussanne, in Switzerland, and his advice to his pupils, previously mentioned. 1800.

1800. Memoriam concerning the Influence of the Air, and several great Substances, on the Germination of various Kinds of Field Plants, in Sweden. 1800.

1800. Gutthard, J. Ch. Geschichte der Landwirthschaft; ein Systematische Lehrbuch für Denkungen, so wie für jeden, der sich dieser Wissenschaft annähern will. 1800.

1471. Crecescioni, Crescenzo, or De Crecescioni; born at Bologna about 1335; died 1380.

1496. Bertochas, Dioneis, of Bologna, who principally treated of very early works at Vicenza.

1527. Castell, Benedict, an Italian mathematician, and the particular friend of Galileo, was born at Brescia, in the year 1527; died about 1566.

1572. Soderini, Giovanni Battista e Bernardo Dava

1574. Garrittus, Nicolò. Storia della Manutenzione del Running Waters; also, Letters and Considerations touching the Draining of Flens,ইতিহাস

1640. Filomelone. Discurso sopra le viticole, e vieti, ó i vini, e le terze seminative, i prat, i boschi, e i giardini, etc. Venezia, vol. 1, a 8vo.

1718. Vinacci, D. Trattato di Agricoltura, nova STOCK adore, 1718.

1722. Teorema. Della Mendicazione del Running Waters; also, Letters and Considerations touching the Draining of Flens, etc. Firenze, 1722.

1783. Delle Piante. Milano, 1783.

SUBJECT 4. Bibliography of the Agriculture of the other Countries of Europe.

9. Arditi, Luigi. Si nota la cultura ad ogni economico del Cinese, a la quale sono state date raccolte delle cause dell'Olio di Cafetria. Padova, 1814, Svo. fig.

10. Tizzoldi, Ott. 2. D. professor of agriculture at Florence, and director of different national establishments there.

15. Giacinti, R. Carlo, professor of botany in Malta.

16. Agricultural Essays, adapted to the Island of Malta. Basic.

21. Brazil, France, etc. Experiments for the. and for the use of the rural poor in a number of the French and for other purposes.

17. Landschop, — parish priest of Saint Miniato.

19. Ferraro, G. A. L'agente in Campania o sia regola esperimentata per migliorare i prodotti e gi: generi di agricoltura secondo le terre del regno d'Italia; con: quando sull'Intelligence e lo imprenditoria. Milano, Svo. 8vo.

21. Reclusi, Costanza. Manuale per la cura dei viti per ottenere la forza di pataca; sulla, su, sull'acido muriatico, sulla peste economica dell' olivo. Firenze. 1815. 8vo.

23. A. At the real institute d'incoraggiamento, etc. De Napoli. tom. 1.

7. Germany and Britain are the only countries in Europe in which it answers to print agricultural books for the sake of the independent readers. In Britain, education is so general among the middling and lower orders, that reading among them is a necessary convenience of life; in Germany, education and reading are equally general and essential: and consequently, in either of these two countries a book will pass through either the county country. But this is not the case with the mass of the people do not read, but books printed there pay, because they are in a language more universal than any other, and perfectly understood by all men of education in Europe. Italian books pay, because they are required for by the agriculturalists of the south of France, all Spain, and in part of Spanish America.

7. Spanish and Portuguese books on agriculture are in much too limited a demand for production. The earliest Spanish author is Herrera, in 1591; and there are scarcely half a dozen since. After the more recent works of a book agent at Madrid, he was only able to send a list of translations, and the transactions of the Economical Society of Madrid; who have also published Herrera's work with notes within the present century. In 1815, a professor at Madrid published Lecciones de Agricultura expedidas en el Jardín Botánico, 2 tomes Svo. An anonymous author, Discursiones sobre varios Plantas Agrícolas. 1 tom. 4to. Of Portuguese books we could hear of none.

7. Of Flemish and Dutch books on agriculture there are scarcely any. These languages are very limited, and very reader in Holland or Flanders understands French or German. Many works have been translated for the Low Countries in Latin and French, but not considered indigenous. The few Dutch works do culture almost all to gardening (Enegr. of G. 1785.) The result of our correspondence with Amsterdam is a nieuwe naamlijst van boeken, Sfe, from which we see little worth taking. Several are written from British works on culture, and and several by the following seem the latest on husbandry.

Magazine of Vaderlandschen Landbouw, door J. Kops, Commissaris tot den Landbouw. 6 deelen compleet met register. 1894.

Amszjav of het verhierter of de Akkerbouw en Landbouwheerezie, in de Nederlanden, door Pro. fessor A. Huchhausen, 2 deelen.

De Boeren Grondin, of kunst, om van verschillende soorten van Landenijen, het meest nut te trekken. door Nienoon, te kunnen bouwen, en andere wetenschappen tot den Landbouw, door J. F. N., turer en J. Kops, met platen.

Of Swedish and Danish books on agriculture, there are necessarily very few; these languages being of very limited use, and the mass of the people too poor to be able to afford to read about ordinary matters, or what they consider as already well known to them. The time such a people give to reading will be devoted to religious subjects, heroic and romantic poetry, or history. The universities of Stockholm and Upsal, every one knows, have produced some useful naturalists: some of these have
written tracts on agricultural improvements, especially on planting fruit-trees (Franzk.-Triid.) and cultivating culinary vegetables (Kirsch-koch Krygd). A few of such works we have enumerated in our Botanography of Gardening (7389), but we can scarcely find any fit to be inserted here as agricultural. The Natural and Chemical Elements of Agriculture, by Count Gustavus Adolphus Gyllenborg, a learned Swedish statesman, were translated by New York Mills in 1770, and may be considered as the prototype of Davy's Agricultural Chemistry. There are several treatises on the culture of the potato in the Swedish Transactions; also on tobacco, on the cultivation of sandy soils, on the cultivation of the Cerealia; and on the hop and plants for fodder.

1826. Winstrup, M., machinist to the king at Fredericksberg, near Copenhagen; Aabildinger af de beskrivelser der er givet ved de forskellige Landbrueker, kc., Copenhagen. 4vo.

To Polish and Russian books on agriculture, it may be easily conceived, there are very few. Some translations from French works were made into the Polish language under Fred. Augustus H; but few or none since that time, the German or French being universally understood by the reading class. Books of agriculture in the Russian language could be of little use. The only things printed in that way there are in the transactions of the Economic Society of St. Petersburg, by foreigners resident there, and in Latin or German. The best informed Russian nobles read French or German like the Poles. There is an agricultural society at Warsaw, which occasionally prints its transactions; and another has lately been established at Moscow, which publishes an agricultural newspaper. [See Gard. Mag. vols. 1. and 2.]

SUBJECT 5. Agricultural Bibliography of North America.

1798. There are a few American books of agriculture, and republications there of most of our best works on the subject. Dean's New England Farmer's Dictionary and Dwight's Travels may be considered as giving an idea of the husbandry of that part of the country, and Roughley's Jamaica Planter of the agriculture of the West Indies. A number of interesting papers on the subject will be found in the transactions of the American, New York, Philadelphia, and other societies.

2. The Method of emulsifying and Observations on the raising and dressing of Hemp. (Ibid. 266.)
1789. Carter, Landon, of Sabine Hall, Virginia. Observations concerning the Flax-weed that destroys the Wheat; with some useful Discoveries and Considerations. (Trans. Amer. Soc. t. 271.)
1790. Dean, Dr. New England Farmer's Dictionary.

CHAP. V.
Professional Police and Public Laws relative to Agriculturists and Agriculture.

1790. By professional police we mean those associations which agriculturists have formed, at different times and in different manners, for mutual benefit or instruction; and also those institutions for the same purpose established by the legislature, or of such a nature as to be considered public or national. By laws we allude to those special legislative enactments which affect more particularly agriculture. These are so numerous that we must refer the reader to his lawyer or law dictionary.

1793. There are few or no agricultural laws of the nature of those of masonry or gardening. In Scotland it would appear something of this kind had existed among ploughmen at one time, as the passwords and initiatory ceremonies are talked of in some of the counties by old men. In Forfar, Kincardine, Banff,
Agricultural societies for interchange of knowledge are of modern date, but they have increased rapidly since 1794: the number at present or lately existing in the British isles is at least equal to the number of the counties. Societies are established, under the authority of government, in almost all the principal kingdoms. These societies are almost wholly supported, and the funds for premiums raised, by the subscriptions of members, and by voluntary donations, legacies, &c.; some, like the Board of Agriculture and the Dublin Society, have received assistance from government.

Of English agricultural societies the oldest is the Society of Arts, founded in 1754 by Lord Folkstone, Lord Romney, Dr. Hales, and Sheelopy. They have published many volumes of transactions, awarded immense sums in premiums, and on the whole done much good. (See Rice's Cyc. art. Society.)

Of Welsh societies there are only two or three, of inferior note, which have been already noticed in the topography of the country.

Of Scotch societies the principal now existing are the Highland Society and the Dalkeith Farming Society.

Of Irish societies the principal are the Dublin Society and the Cork Institution.

The future progress of agriculture in Britain.

The improvement of agriculture, like that of every art, manufacture, or commodity, necessarily depends on demand and production: a powerful and effectual demand will ensure produce, and excellent produce will, to a certain extent, create demand. A general nicety of taste in coach and saddle horses will call forth a superior description of these animals, and superior animals will tempt purchasers; if the inhabitants of any district who live chiefly on barley or oats indicate a preference for wheat, and a willingness to pay for that grain, wheat will be produced, and so on. Again, as the object of every individual who engages in art or trade is to acquire gain, the advancement of an art will depend mainly on the profits it affords; an art or occupation which affords less than the average profits on capital will only be followed by such as, from habit or other reasons, cannot apply themselves to any thing better, but extra-profits
will command both capital and skill. From these considerations it is obvious, that the improvement of agriculture depends on the profits on capital employed in it, on the taste of those who purchase its products, and on the knowledge of those who are engaged in agriculture as a profession. The first subject would lead us further into political economy than would be of much use in a work of this kind, and therefore we shall limit ourselves to a few remarks on the other topics.

Chap. 1.

Improvement of Agriculture, by refining the Taste of its Purchasers, and increasing the Knowledge of Agricultural Patrons.

1792. The desire of being comfortable is the first step towards improvement; but before any thing can be desired, we must know what it is. If, when they know of nothing better, rest satisfied with what they have; and therefore one of the main sources of improving the taste both of those who purchase agricultural produce from necessity, and of those patrons of agriculture who purchase from the conjoint impulses of necessity and choice, is the increase of knowledge. However paradoxical it may seem, discontent is the parent of all improvement, as certainly as the acorn is the germ of the future oak, or the time present that of all future times. The grand achievement of the present age, an eminent writer observes (Examiner, Jan. 9, 1831), "is the diffusion of superficial knowledge;" and on this diffusion, superficial though it may be, the progress of agriculture and of every other art depends far more than on anything else.

1793. In Scotland and Ireland a taste for wheaten bread and butcher's meat be introduced generally among the operative classes, the advantages to agriculture would be immense. Could the same persons be taught to desire a greater degree of cleanliness, light, and warmth in their cottages; a greater variety of potatoes, salads, fruits, and flowers in their gardens; a greater care in the disposition of these flowers, and in the education of their sons and daughters, how great the general benefit! Much may be done to bring about this change, by the opulent who are willing to reside on their estates and to take a little trouble. Building good and comfortable cottages; attaching proper gardens stocked with trees and plants from the demesne; and to their immediate or distant influence, little premiums, or marks of distinction for keeping them in the neatest order, and for decently clothed well-bred children, would soon have a sensible effect. Attending to that kind of education which consists in teaching infants civility and politeness, with mutual respect and restraint as occasion requires; and laying a foundation for many things, the first step in every thing like persons in this respect. These improvements in the taste of these第一步改进会导向政治经济，但当我们知道没有更好的，会满足于现有的一切。因此，首要的来源之一是增加农业知识。虽然这可能是悖论的，但不满意是所有改进的父母，正如橡子是橡树未来的种子一样，亦或是时间的父母，亦或是所有未来的时间。古代的伟大成就，一位著名作家在《观察者报》(Examiner, Jan. 9, 1831)中指出，“是浅薄知识的扩散；”而这种扩散，即使是最浅薄的，也可能带来农业的进步和所有其他艺术的进展比任何其他东西更依赖于此。

1794. 在苏格兰和爱尔兰，对于燕麦面包和肉食的品味被引进一般地普及于操作阶级，对农业的益处是巨大的。如果同样的人们能被教以更大的清洁度，更亮的光，更暖的热，在他们的小屋里；更大的土豆、沙拉、水果和花朵在他们的花园里；对这些花朵的更精心的布置，和对他们的儿子和女儿的教育，多大的好处！许多事情可以这样做以带来这种变化，由富裕的人们愿意住在他们的地产上并且愿意花些小麻烦。建造舒适的房屋和舒适的花园；在小园子中种植树木和植物；对它们的近邻或远邻有好处，或者小的奖励，或者由于他们立即或间接的影响的标志，都有助于保持它们的整洁。坚定的教育，包括教婴儿礼貌和礼貌，互相尊重和自克制作为必要时的步骤；和对可以为所有人的基础，第一步的每一件事都包括在内。这些问题的改进对这些人的影响将是巨大的。

1795. 在苏格兰和爱尔兰，对于未来海洋的求知欲，将是最大的。“在所有未来的时刻，是一切的基础。” ——在苏格兰和爱尔兰，对于未来海洋的求知欲，将是最大的。“在所有未来的时刻，是一切的基础。”
Chap. II. Improvement of Agriculture, by the better Education of those who are engaged in it as a Profession.

9730. By education it is generally understood that portion of knowledge which is obtained at schools; but in a more extended sense (as Mills observes), it may be defined the means which are employed to render man competent for pursuing the part which he undertakes to perform in life, with increased satisfaction to himself and others. Education may thus be considered as extending to every thing which operates on the body or mind, from the earliest periods of our existence to the final extinction of life. It is unnecessary here to embrace the subject in its full extent; but we shall offer some remarks on the education of practical men in general, on the professional education of an agriculturist, and on the general conduct and economy of his life.

Sect. I. Degree of Knowledge which may be attained by Praclical Men, and general Powers of the human Mind as to Attainments.

9731. The kind and degree of education that we think ought to be given to every human being in this and in every country, and in every state of civilisation, may be thus defined:—All the knowledge and accomplishments that a child's body or mind, and the state of knowledge and the art of teaching at the time, will admit, previously to the age of puberty; giving preference to those branches of knowledge considered most useful, and the accomplishment of which is most difficult, by the wise and good of the age. It seems unreasonable to employ any child in aiding to procure the means of its subsistence, or that of its parents, before the age of puberty. Previously to that age, among savage inhabitants of the present species of the world, in modes of teaching, all that is worth knowing may be taught more effectually than common reading, writing, and arithmetic are, during the same time, by the common methods. Man, so trained and instructed, and living under an enlightened government, will become as different an animal from what he is now present, even in Britain, as the most enlightened modern moralist and philosopher of the time is from an African savage. "It is not necessary," says Lequinio, writing in 1792, "to render an agricultural labourer a learned man;" but I am well assured, from my own experience, that the knowledge of every thing useful, and of much that is agreeable, both in knowledge and manners, is perfectly consistent with a life of labour in the fields. But hitherto the education of the labouring classes in the country has proved rather an obstacle to the development of reason than otherwise. Eight or ten years are employed in filling the head of a child with chimeras and prejudices, which twenty years of study will scarcely succeed in entirely removing out. It remains for national philosophers to explain what is national evil; and we shall one day have under the thatched cottage of the country hamlet thinking men endowed with reason, and capable at once of taking a part in the political and moral affairs of their country, and holding the plough or guiding the cart on their own form. "Il faut," says this admirable writer, "que les premières leçons soient l'apprentissage des droits de l'homme, et qu'ils soient enseignés sans aucun mélange des perdides principes du fanatisme et des fruits barbares des gothiques préjudicés, de quelque espèce que ce puisse être. Les notions de la raison et du bon sens tombent sous tous les intellects. Les droits de l'homme intéressent tous les individus, et l'esprit et le cœur sont libres pour s'accorder pour son faire une science impérissable; graves une fois, je le repete, ils ne s'effaceront jamais; ils se concèveront avec aisance, et ils se fixeront bien plus solidement que ces antiques assertions données sur la foi d'autrui, et transmises à travers les siècles des siècles les plus obscures; assertions ridicules, et qui, peut-être, n'ont seulement pas en leur la simple vraisemblance; ils se fixeront, sur tout, parce qu'ils seront assurément et avantageusement comparés à toutes ces fausses théories et fables dont le n'est alors éclatant pour tous, et parce qu'ils seront encore plus avantageusement mis en parallèle avec ces mystères et ces sottises dont on se dépourvoit tout autant de l'intelligence et de sa raison. C'est par ce simple enseignement que s'élèvera tout d'un coup dans nos campagnes une espèce raisonnante et libre. Sortie, par cette création morale, du cahos ténébreux, et de l'existence littéraire de ces société où nous avons des siècles dans les villes, des siècles dont les habitans ne se souvenaient, l'espèce humaine qui se prétendaient de la dominer, nous la verons une race nouvelle, intelligente et hardie, laisse un espace incomparable entrela et les générations qui la précédèrent."

(Les Préjugés abrégés, par J. M. Lequinio, Paris, 1792. Paroissial Institutions; or, an Outline of a Plan for a National Education Establishment, &c.; and Des Établissements pour l'Éducation Publique en Île-de-France, dans le Pays de Deau.)

9732. A high and equal degree of education has some powerful advocates in North America, and, it is thought by many, will, at no distant period, be adopted in several of the states. The New York Daily Sentinel and the Working Men's Advocate are two of several newspapers which support what are called "working men's measures." Among these the first and most important is a "republican education, free for all, equal for all, and at the expense of the state: embodied every branch of useful instruction, moral, intellectual, and operative, and extending to the entire protection, maintenance, and guidance of children and youth, male and female, without distinction of class, sect, or party, or reference to any of the arbitrary distinctions of the existing state of society." (See Essays on Public Education, New York, 1830; Cooper's Lectures on Political Economy, as quoted in the Spectator, Dec. 4, 1830; and Gard. Mag. vol. vii.)

9733. This high and equal degree of education we consider to be as much the birthright of a child in a country as there is a higher degree of civilization, as food and clothes are to a man or woman in a country, without a fair chance of being able to procure those means of subsistence and of happiness which belong to human nature under the given degree of civilization; in short, without a fair chance of making the most of life. To introduce an igno- rant, and ill-instructed, and highly civilised child, under the axe of industry, and the hammers of prosperity and happiness, would be more absurd than to turn an educated child into a country of savages. This is one view of the subject, and it is a view on which all who can afford the expense act with some justice. But we have often observed, and consider, that the children of different classes, if we regard them, will be as much an object of society with another, this principle will equally dictate the duty of bestowing, as far as practicable, that good on others which we feel to be a good in ourselves, and which we are convinced would add to the general happiness. Viewed as a matter of public policy, and considering that the grand object of every government ought to be, with reference to each of its subjects, their happiness and prosperity; and, with reference to other governments, its own stability; reason dictates the use of the most important means for gaining these ends; and that it would be prudent, no less than just, in government so to legis- late, that as every individual subject should have the degree of education above defined. Let none,

STATISTICS

The miners and leadhills have a regular library and reading society; and the works they make choice of are not only divinities, voyages, travels, &c. but even works of taste, such as the British classics, and best novels and romances. The degree to which knowledge will prevail among any class of labouring men will depend jointly on their own ambition, on the demand for knowledge, on the reputation of the workman, and his desire to know more what enables him to supply the ordinary wants of life; but where the workmen of any art are required to have technical knowledge of any particular kind, they will be found invariably to possess it. Thus carpenters and masons, or some knowledge of the strength of materials; and these kinds of knowledge are acquired by them without an interval's interruption of their daily labour: on the contrary, the habit of evening study renders them more steady, sober, and industrious than other workmen; than bricklayers and paper-hangers, for example, whose employment requires a much less intellectual skilful. If every cook-maid, before she could obtain a first-rate place, were required to be able to read Apicius in the original tongue, there would be no want of learned cooks; and if no bailiff could obtain a first-rate situation who had not written a hist. of Greece, or Latin, he had not made the allowance of bailiffs so qualified. A Caledonian, when he comes to the low country, soon acquires the English tongue, and, if he has been taught Latin, thus knows three languages. The servants at the inns on some parts of the Continent, frequented by different nations: there may be a mildewed gold, a later gentleman: the office on the island of Cronstadt spoke and wrote ten languages; and the bar-maid at the hotel de Londres, at which we lodged in Moscow, in 1814, could make herself intelligible in Swedish, Russian, Polish, German, French, Italian, and English.

7941. The certain way of obtaining any thing is to be impressed with the necessity of possessing it, either to avoid the evil of being without it; or to satisfy the desires of others as to ourselves; or our own desires. There is scarcely any thing a rational man can desire which he cannot obtain, by maintaining on his mind a powerful impression of the necessity of obtaining it; pursuing the means of attainment with constant and keen desire, that enthusiasm and ardour which always accompany powerful desires. All may not acquire, by the same degree of labour, the same degree of eminence; but any man, by labour, may attain a knowledge of all that is already known on any subject, and that degree of knowledge that many may not think fit, to any man. 7942. The great drawback to every kind of improvement is, the vulgar and degrading idea that certain things are beyond our reach; whereas the truth is, every thing is attainable by the employment of means; and, nothing, even the knowledge of the common hall, is so moving as to wish for, and to which the most are only desired by men of extraordinary minds; but let no man fancy any thing is impossible to him, for this is the bane of all improvement. Let no young ploughman, therefore, who reads this, even if he can but barely read, imagine that he may not become eminent. There are two circumstances of some importance to the young agriculturist, let him never lose sight of this principle—that to desire and apply is to attain, and that the attainment will be in proportion to the application.

 Sect. II. Professional Education of Agriculturists.

7943. In order that a professional man should excel as such, every other acquisition must be kept subordinated to that of his profession. No branch of knowledge should be pursued to any extent that, either of itself, or by the habits of thinking to which it gives rise, tends to divert the mind from the main object of pursuit; something, it is true, is due to relaxation in every species of acquirement; but in the intellectual and moral relations to which we are vitally connected, and more particularly, for the purposes of educating an agricultural community, we mean that direction of their faculties by which they will best acquire the science and manual operations of agriculture, and we shall suppose agricultural pupils generally to have no other scholastic education than some knowledge of reading, writing, and arithmetic.

7944. All young men who intend embracing agriculture as a profession, whether as ploughmen, bailiffs, stewards, land-values, or rent-paying farmers, ought to undergo a course of manual labour for one year or more in order to acquire the mechanism of all agricultural operations. When the pupil is not destined for any particular county, then he should be sent to a farmer in a district of mixed agriculture; as, for example, East Lothian, where he would, if placed in a wheat and bean culture farm, see at no great distance the turnip system and feeding; and if put in a district where a few miles of hill separate him from any particular county, he ought to be sent to a county as near as possible of similar soil and climate, where the best practices are in use; as from all the turnip counties, pupils should go to Northumberland or Berwickshire; from the clay counties to East Lothian, or the Claymore and the Cheviot district to the Lowland district. 7945. The term of apprenticeship completed, the future time of the pupil ought to be regulated according to the ultimate object in view: if he is intended for a ploughman, shepherd, or herder, perhaps to the same district, in order not merely to acquire but to habituate himself to all the improved operations and practices. If he is intended for a bailiff, then, after having been two years on one character of farm, let him engage himself for a second two years in a district of an opposite or at least of a different character. There are, as already shown, only three descriptions of farming in Britain: the bean and clover, or clay-land farming, which includes feeding by soiling; the turnip farming, which includes feeding both by soiling and pasturage; and the hill, or mountain, or pasture farming, which includes the formation of breeds. Three varieties of branches of farming, if choose to become those that may be described the engineering, valuing, and estate-agency departments, can only be completely acquired by first going through the course above described, as suitable for bailiffs and common stewards, and next placing themselves under an eminent steward, land valuer, drainer, road engineer, &c. As, for example, there is a farm which has extensive woods and plantations, and also, if possible, some quarries, fisheries, or even mines under his care, and of a land valuer or drainer in full employment. When a solid foundation is laid by a thorough practical knowledge of all the operations of common agriculture, the higher branches of business and of confidence will be opened; but, on the contrary, when young men who know nothing of common country work are sent direct from school, or from an attorney's office, to a land steward or agent, in order to acquire the art of managing landed estates, the worst consequence may be the result; the property of the county is in the hands of young men who have never set foot on the soil. The condition of these estates and tenants, managed by attorneys, may be referred to in proof of our assertion.

7946. Young men intended as real-paying farmers, after two years' labour as common stewards, should be kept as assistant bailiffs on other farms, till they are at least 25 years of age: no young man, in our opinion, ought to be put in a farm on his own account, or employed as a master bailiff, at an earlier period.

7947. In all cases when young men are destined for particular purposes, they should be sent chiefly to particular districts; as, for example, young men intended for road-surveyors, to where roads are best managed, drainers to a draining country, embankers to Lincolnshire, warpers to the Humber, irrigators to South Cerney, hedges to Berwickshire, woodmen and foresters to Dunkirk, or Blair in Atholl. It
would contribute much to the improvement of agriculture in the backward counties, if landed gentlemen would prevail on their tenants to send their sons as apprentices, or even as ploughmen or farm labourers, to the improved counties; or if lords brought up by the parish were sent there with a view to their acquiring a taste for the improved state of the improvement.

799. Whatever is the kind of professional knowledge to be acquired, the means of attainment is the pupil's paying such attention to what he sees and hears as to fix it in his memory. One of the first things, therefore, that a young man should do is to cultivate the individual power which he can only attain to by dint of practice. First look at inconvenient things, then shutting his eyes, and trying whether he recollects its magnitude, form, colour, &c.; whether he would know it when he saw it again, and by what special mark or marks he would know it or recognize it. When he goes from one part of the farm to another, or is on a walk or journey, let him pay such attention to one thing as shall enable him to give some account of them when returned from his walk or journey; and let him try next day, or some days afterwards, if he can recollect what he had seen then, or at any particular time and place.

800. **The attention to be exercised in such a way as to impress the memory, and enable the observer or hearer, not only to recollect objects, but to describe them, must be exercised systematically. A thing or a discourse must be attended to, not only as a whole, but as a composition of parts; and that the parts must be considered in order of their occurrence, their tendency, their force, and their relative situation and position. To be able to give an account of a town or village, for example, the first thing is to get a general idea of the outline of its ground-plan, which may be done by looking from a church tower or adjoining hill; but, its relative situation to hills, woods, or waste places, and in what quarters; next, the direction of the leaving street or streets must be noticed; then the intersecting or secondary streets, the principal public buildings, the principal private ones, where the lowest houses and narrowest streets are situate, and what is the character of the greatest number of houses.**

801. **To treasure up in the mind the characteristic marks of particular varieties and sub-varieties of stock is a most important part of an agriculturist's professional education. To do this effectually, some knowledge has to be acquired by every person, of the situation and position in which he has been, or is, to be at any time.**

802. **In connection with professional studies, the pupil may find it necessary, if his education has been neglected, to go on at his leisure hours with all the usual branches of education, either assisted by books along with a teacher. It is for the best advice and education present, or procure such a man as comprehends, measurement, mathematics, and drawing, he should occupy himself in acquiring a knowledge of botany, zoology, geology, and mineralogy, without a tolerable knowledge of each of which he will ever be in the dark among modern agriculturists, and it will be in reading books of great subjects that, if any relation to agriculture, and store his mind with all he can acquire from one of the best general Encyclopaedias, as that of Rees, or the Encyclopaedia Britannica, with its excellent supplementary volumes. If he will go farther, and wishes to know the extent to which he may go, he may consult what we have advanced on the subject of education in the Encyclopaedia of Gardening.**

**SECT. III. Conduct and Economy of an Agriculturist's Life.**

803. **A plan for the general conduct of life should be fixed on by every one when he arrives at manhood, and steadily pursued for the time to come; most commonly such a plan is formed by the son soon after the child's birth, and, at the latest, when the boy is taken from school. The boy arrived at manhood, however, is entitled to examine this plan, and amend it, or devise another more congenial to his own situation; but the risk of any change of this sort by persons so young and inexperienced is so great, that no youth ought to venture on it without the utmost consideration, and the firmest persuasion in his own mind: where the parent has done his duty, such changes of plan will not often be attempted; for, by the early infusion into the mind of a child, is introduced a relative to that person, a taste for the pursuit or employment of his own; an individual who has been taught to look after himself, who has been so accustomed to think of his own comfort as to have broke and taken the head. In such cases, the parent may generally conclude, that where the pursuit or purpose is not bad, the force of natural inclination will be more likely to command success than the influence of parental authority; and that a prudent or business, wise, and sober, will be more tolerable and respectable business followed by any one against his inclination.**

804. **The plan and conduct of life are in most cases determined by accidental circumstances. The son of the labouring man grows up without any regular training or education for a particular end, and finds himself at the age of manhood engaged in rural labour, and apparently incapable of any other; his notions and his ambition are so limited that he dare not venture to desire a change for the better; for many ever desires that which he thinks is impossible to attain, and the more it is impossible, the more powerfully it restrains the attempt at improvement. The life of the ploughman or labourer, as much as it differs from that of a man of eminent natural powers and superior education, is capable much amelioration by being directed to a suitable end or object. The ultimate object of the whole may, I think, be observed (Encyc. of Gard. 2d edit. 1778), as predestination, as conduct is fate.**

805. **The greater part of mankind enter on life without any fixed plan or object in view, or, if they have some notion of one or other, it is general distinction, they form no plan by which it is to be accomplished; the consequence is, that such persons, after blundering on through their best years, arrive at the end without having gained any thing but experience, no use to them. No man is born in possession of the art of living, any more than of the art of agriculture. He receives one curvature or the other, or both, and the practice to be studied as well as the theory, and a man can no more expect permanent satisfaction from actions performed at random, than they would from the arts of navigation or surgery. The poor man of a large family, the result of too early marriages; how many find themselves arrive at old age with no other resource for support but charity, the consequence of want of foresight in expenditure; how many are suffering under poverty, brought on by their own want of frugality or negligence; under diseases, and excesses committed in the heyday of life: and how many among those not born to inherit property, who, at no period of their life, have any other alternative between hard labour and deficient food, than disease and want!**

806. **A plan of life may not in all cases be the cause of all this misery, because accident enters into life for something, both on the unfavourable as well as the favourable side of the question; but we have no hesitation in asserting, that want of plan, as a cause of misery, is ninety-one to a hundred; any plan at all, even a bad plan, is better than none; because those who set out on any plan, in all probability, sooner discover its errors if a last one, and correct them, than those who set out on no plan.
2050

STATISTICS OF AGRICULTURE.

PART IV.

discover the want of one and form a good plan. The young man who is just setting out in life may well tremble at the consequences of proceeding on the journey without the guide of a judicious plan; this plan he must form himself, because he alone feels what he wants, and what he can do to gratify them; all that we can offer are a few hints.

7876. In order to be able to form a plan it is previously necessary to determine the object to be attained by it. Happiness is the object of every action of human life, and consists in the gratification of certain wants and desires; some of the more particular to the wants are pecuniary, and it is by the most equitable and justest means that have been devised that a man is enabled to procure the gratification of them. There are, however, other wants and desires which cannot be procured by the means of money; such are the wants of comfort and happiness.

7878. Independence is the grand object which every man destined to live by the exercise of his labour or talents must have in view. It is his aim at every period of life, when the imagination is vivid, and health and talents are in full vigour; it is the object that most naturally presents itself in the mind, and it is this that we mean when we say: a man in this case is said to arrive at independence, instead of want, as in the case of the savage, or of beggary, as in the case of the improver.

7879. Independence is the grand object which every man destined to live by the exercise of his labour or talents must have in view. It is his aim at every period of life, when the imagination is vivid, and health and talents are in full vigour; it is the object that most naturally presents itself in the mind, and it is this that we mean when we say: a man in this case is said to arrive at independence, instead of want, as in the case of the savage, or of beggary, as in the case of the improver.

7880. The character of his profession is the most rational mode in which an agriculturist, of whatever grade, can pursue independence. Only extraordinary circumstances can justify a change of profession; in common cases the advantages of change are always equalled by the disadvantages of it. The man who has been educated to agriculture is most likely to be contented with it, and most commonly attracted to want of skill; it is better, therefore, to pursue unremittingly the profession to which we have been educated, even though we should not be very successful in it, than to risk an infringement on character by adopting another. The practice of agriculture is, as we have said, the same as that of any other class, serving, commercial, and artist agriculturists: on each of these classes we submit a few hints to aid them in forming a plan of life, and regulating their expectations.

7881. The greater number of agriculturists must ever belong to the lower grades of the serving class; and act as ploughmen, herdsmen, shepherds, hedges, woollen, and labourers of all work. These form the greater proportion of mankind in every civilised country, and must ever remain the bulkiest material in the social fabric. Comparing one age and country with another, we may conceive that the greatest difficulty in the progress of the human race is to remove the ploughman from his horse.

The ploughmen in different parts of the country are as intelligent as their employers: in Scotland they have the Bible by heart, and familiar with the history of their country, and not ignorant of its literature; they are a laborious and industrious people, who always do their best. Hence it is that they do not fear the hand of time, and till the latest period; they are almost always independent, either from their labour, their savings, or, in old age or sickness, from the assistance they receive of their children in return for what was laid out on their education. These men are an army, comparatively by their capacity, against which new generative force is weaker, because the measure is smaller, as full as the largest; for the essential materials of comfort and happiness are the same in all classes, and in all classes a man's wants and wants accommodate themselves to the means of gratifying them. The rich have no wants, and their desires are such that no other expression than gratified; the pains and pleasures of life are neutralised into a kind of insufficiency, till ennui brings on disease, which to this class becomes a blessing, by procuring for them the occupation of taking medicine, the duty of attending to the doctor's regulations, and the pleasures of convalescence.

7882. Constant labour, even that of the humblest description in the country, when it is not oppressive, and where it is accompanied with abundance of food, sufficient clothing, and good health, is by no means inconsistent with happiness. It is a common but most erroneous idea, that happiness is confined either to the rich or the poor. To the rich, poverty is the spring of activity and industry which is unquestionably more miserable than any ploughman in the empire. "Happiness," says one who has thought much on the subject, "is the full and vivid satisfaction of the mind; and it consists in content and uninjurious enjoyment, that is, enjoyment not accompanied by changes of body or mind. This is the satisfaction. It will readily be perceived, is employment, either bodily or mental; and the more energetic, without exhaustion, is the employment, the more full and vivid will be the satisfaction. The human mind is naturally active; and, except in sleep, if even the smallest degree of employment becomes torpid, or torpidity comes, the blood is to the body. Employed it must be, to know content or feel enjoyment; for, by any want productive of pain, either bodily or mental, especially the latter, content and enjoyment are, according to the degree of the pain, destroyed or diminished; and the want, which the unemployed mind invariably feels, is as innately productive of uneasiness, or tenderness, as attainted, mental pain. Indeed this pain is, not infrequently, altogether unendurable. 'All the importunities and perplexities of business,' says Dr. Johnson, 'are softness and luxury compared with the importunities of service and the activity of insignificance; the unsatisfactory conduct and tedium of idleness, and the business of this imperfect life, this is intolerable.'

7883. The life suitable for the operative agriculturist may very well be founded on the condition of this class of men in the northern counties of Northumberland, Berwickshire, East Lothian, and others. We have already [7881] and [7884] described in general terms the manner in which farm servants are lodged, dined, and served; these particulars will be found in detail by those who consult the sixth volume of the "Gardener's Magazine" p. 898.

The essence of the mode consists in the employer providing the employed with comfortable cottages and gardens, and paying them chiefly in the necessities of life, in so much meal or flour, so much ground to grow potatoes and flax or hemp, a cow's keep, the raising of so much wool, so many sheep, or so many hogs; or such crops or cattle as the farmer may need for his farm, and a certain proportion of money. By this mode of payment the operative countryman is always sure of a comfortable home and food, sure of milk, butter, meal, bread, and potatoes, the produce of a piggery, and of the gardens; and the greater part of the expences of his gardener, and the more of these articles in the public market. These good things can only be rendered nugatory by the evil of a bad wife. All country servants hired by the year might be accommodated and paid more or less in this manner; and to this mode of life and paying they might be reduced, if they ought to be so reduced. So the scale of operative agriculturists.

By prudent conduct, in regard to the increase of their family, and by frugality, they may live in decency and comfort, educate one or two children, and save something for old age, or unforeseen occurrences.
The Northumberland ploughman is the happiest of labourers, and never feels a bad season. His wages are paid weekly; and with frugality and care, his wife may bring up a large family upon this income. The reverse is sometimes the case, but it is attributed to the wife who washes the produce of the cow. The small stock of the hind being always his own, and the cow generally so, makes him prudent and careful service to save as much of his wages as will set him up for himself. To this, and the fact that the native of the northern coast, the enviable state of the Northumbrian labourer to be attributed. It operates to a preventive, and care upon the population, which beautifully illustrates Mr. Malthus's theory; or, in the words of Burns, it teaches them to "know their place.

They are all anxious to give their children such education as they can command. When they are within the reach of a charity school, and can secure a scholar, they send their older, work and save the wages of summer to pay for putting themselves to school, but leave the major part of the agricultural labourers of England are excluded; they till indeed, but it is to continue, but to better themselves."

ECONOMY

The day labourer who has no particular employer, a fixed remuneration is instead of a comfort less than he can exist on, nor he who may be enabled to do without parochial relief, and bring up his children decently, it is as much as could be expected, that the temporary loss of employment, he is in general totally unprepared; he thinks not much of the narrow resource of the indigent; perhaps, for him that he does not anticipate evils which he cannot prevent. Every one knows how beneficial to the community, how advantageous to the individual, the hope of bettering his condition in life: it cheers him in adversity, encourages his industry, provides him against sickness, and makes him live. The major part of the agricultural labourers of England are excluded; they till indeed, but it is to continue, but to better themselves."

The Scotsman's view of the position of the agricultural labourer. The condition of the agricultural labourers has lately been considered by the editor of the Scotsman, in an article in his sixth volume (Nos. 1131, and 1132.), which is also published separately in a pamphlet entitled The Scotsman's Advice to the Labouring Classes. The condition of the agricultural labourers, it is observed in this pamphlet, may be deteriorated as follows: 1) by increasing their numbers too rapidly, and by diminishing the capital which provides them with employment; this is either diminished, or its natural growth is impeded, by the enormous sums paid to the government, by the tax on wine, and the benefit of the aristocracy, and by the many absurd restrictions on industry, which have arisen from the ignorant legislatures. To repeal or reduce taxes, and relieve industry from the restrictions which fetter it, benefits the working classes by exchanging the fund of wages and the demand for their labour. The sufferings of these classes, in no small extent, imputable to the misconduct of government. Culpable and injurious, however, as the extravagance of the government has been, I am of opinion that all were the results of folly, and all the obstacles to freedom of industry removed, the relief given would be but temporary. The misconduct of the working classes might be mitigated by such means, but it cannot be eradicated by legislation, nor by any human wisdom. The difficulties are of the order of life, and the obstacles to freedom of conduct are as much entrenched in the laws of natural life, as are the obligations it lays upon them. This applies to the middle ranks as well as to the lower. Thousands and tens of thousands marry every year whose earnings hardly suffice for their own subsistence; and multitudes throw their offspring on the world "with as little rational consideration about its future well-being, as the crocodile shows when she drops her egg in the sand, and leaves it to the sun and the waves to hatch her young into life." Such persons shelter their thoughtless conduct under the plea of trusting Providence to bring them through their school without parents, or in the claim that the work is not conducive to their health and mischief. Self-control, the consequences of the acts, and endowed with powers which, it rightly used, would make them great masters of their own destiny.

To convert the barbarians which marriage brings with it into money, the Scotsman suggests the following scheme: he takes the case of an industrious mechanic beginning to earn fifty pounds a week at the age of eighteen, and he shows what he could accomplish by living economically, and deferring marriage till he is twenty-eight; he supposes him able to live upon 12s. 6d. per week, and to place 3s. 6d. per week in a savings' bank, at 6 per cent. interest, will have 100l. in ten years to 50l. at marriage. He is supposed to spend 30l. of this 100l. in furnishing a house, &c. and to dispose of the remaining 70l. to provide against the following casualties. The money thus provided against sickness, which may be done by a weekly contribution of 5d. for himself and his wife.

The second casualty is the infirmity of old age. This is to be provided against by an annuity from the government, or a benefit society; and 17s. 6d. paid at once, or an annual payment of 9s. 6d. by a man at the age of twenty-eight, we obtain an annuity for him of 20l. per annum for whatever number of years he may live beyond the age of sixty-eight. He may do by paying 15l. 10s. 8d. for which he may secure for his wife, supposing her age to be the same, an annuity of 1l. 10s. for life, in the event of her being left a widow, whatever may be the case with the other. On this subject the benevolent and philosophic author of the scheme observes, "When society is more enlightened, it appears to me that a provision against the chance of widowhood will be considered as indispensable."

The fourth casualty is the chance of the death of the father before his child is able to shift for itself; that is, before it is fifteen or sixteen years of age. To ensure each child against this casualty, it is proposed to provide for the parent, 3s. 6d. per week, for time being, to be paid up to the child's fifteenth year. This, the father being aged thirty, he calculates may be purchased for 50l. paid down at the first year of the child's life. "A similar deposit of 5l. would be requisite at each addition made to the family; and as a married man is assumed to produce on an average four children, the whole sum expended under this head would be 20l.

Those who have more than four children must make extraordinary exertions.
STATISTICS OF AGRICULTURE. Part IV.

7973. A reasonable degree of security against the casualties of life may be afforded to a working man about to enter into the married state and his family for the sum of 10l., which is shown he might save by the age of twenty-eight. That sum would be disposed of thus:

<table>
<thead>
<tr>
<th>Description</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Furniture, exclusive of what was provided by the wife</td>
<td>£25</td>
</tr>
<tr>
<td>Annuity for himself of 5l. per annum</td>
<td>£17</td>
</tr>
<tr>
<td>Annuity of 10l. per annum for his widow</td>
<td>£33</td>
</tr>
<tr>
<td>Provision for four children</td>
<td>£20</td>
</tr>
</tbody>
</table>

Therefore, let no man whatever, not even the most humble country labourer, think of marrying before he has saved 10l.; and let him beware, before he is spending any part of that sum which is allotted for his security, of the four casualties of the married state.

7974. To carry this scheme into effect, mutual assurance societies by the working classes themselves, or the benefit societies, would probably be the best mode, and government and the more wealthy members of society, no time to lose in establishing in their formation, which can be too often inculcated upon the working classes, that the improvement of their condition must be their own work. Were this scheme carried into practice, "it would diminish their numbers relatively to capital, and as a consequence, their wages would rise. Secondly, it would rescue them and their families from extreme poverty, give them independence of character, secure to all of them the advantages of education, and thus break down the barrier which confines them to the sphere they are born in, and precludes them from obtaining any of the higher prizes in the lottery of life. To society the system would be equally beneficial, poor's rates, with all the abuses they conduce, would be done away; crime would be rare when pauperism is eradicated; and by the universal diffusion of education, all the talent in society would be made available.

And last not, when every grown-up man had either a small stock of savings, in hand, or investments in a common fund, we should have the very best guarantee for the public tranquillity. Did the working classes fully understand this scheme, its excellent author continues, "nine tenths of all the poverty, misery, and crime which we see around us would disappear; we should in fact find ourselves in a new world, full of intelligence, peace, and good order, in which life and property would be as surely and more secure, happiness be more, and an admirable foundation laid for the further amelioration of the lot of mankind."

7975. The plan of life for the directive class of agriculturists need hardly be pointed out; the rise from a farm labourer's bailiff, or from a demesne bailiff or steward, to the possession of an estate, is an obvious object of ambition. In another direction he may rise through the different gradations of the commercial agriculturist, or, adopting the rank of counsellor or artist, he may become a salesman, appraiser, timber or land-surveyor, land-value, agent, or agricultural engineer; rarely, however, is the vetere priest, or that gentleman, professional.

7976. The remuneration to which a directive agriculturist is naturally entitled, should be regulated by his professional abilities and experience; that which he will commonly receive will be regulated by the quantity of his capital and experience in the market, his always keeping his conduct and merits as low as possible will render it worth his while to be honest, assiduously attentive to the interest of his employer, and of polite and obliging manners. A handsome salary to such a servant is wise economy.

7977. The object of the artist or counsellor agriculturist is to rise to the rank of author or professor, conditions of more honour than profit; or to realise property and become a proprietor cultivator. For a rent-paying farmer, no artist or author is at all adapted.

7978. The legitimate object of a commercial agriculturist is to rise in the different grades of his class, and become either a large farmer, a gentleman farmer, or, best of all, a proprietor cultivator.

7979. The profits to which a commercial agriculturist is entitled, comparatively with those of other commercial men, are theoretically determinable by the risk attending the employment of his capital, and the skill requisite to prosecute his art; but, practically, this will depend on the proportions of land and capital in the market. The risk attending capital employed in the culture of the useful products of the soil, is evidently less than the risk of capital employed in many or perhaps most manufactures; and the skill requisite to enable any one to become a farmer, according to the customary practices of the country, is required for only a little longer than the revenue of these things, are men everywhere ready to become farmers; hence the profits of farming are naturally less than those of most other pursuits; but, to balance this, the farmer has security for life; the second, the tenant farmer.

First, it is impossible to give a certain degree of consequence from its connection with a considerable group of offices, surrounded by a garden, orchard, fields, woods, and other rural security, all in his occupation, and inhabited by servants in cottages, horses, cattle, sheep, and other domestic animals, in subjection to him, gives him a security both real and apparent; and he is the owner and to the possession of that sort of rural retirement and independence which is the object of almost every commercial man's ambition, than any other mode of life could do. Secondly, many trades and professions preclude (according to general prejudices) their followers from being gentlemen; whereas, though every farmer is not a gentleman, yet any gentleman may become a farmer, without in any degree lowering his rank and character; a farmer may, therefore, if he chooses to adopt the habits and manners of a gentleman, be reckoned as such. Thirdly, the farmer's products are in universal demand, and he is sure of a market at some reasonable rate, a fact otherwise with many manufactures. Fourthly, he is sure of a home, of the necessary of life, and, in general, of most vigorous health. Fifthly, he is generally a man of more parochial influence than the tradesman or manufacturer.

7980. Farmer makes war with his protégé. The utmost exertions of the most skilful and industrious men, in the most improved districts, seldom do more than enable them to keep pace with the times; and the great majority, in all countries, lead a life of great labour and anxiety, and end as the bagmen. No farmer, in a general way, can raise more than one crop a year, and in this respect the farmer of Russia and Poland has the advantage of the British farmer, for the lands of the former being from five to eight months under snow, all root-weeds are destroyed, and the ground so loosened by the frosts and thaws, as to require very little stirring for the seed: the rapid summer which successively ripens all annual plants that will grow there, nearly as well as in England, and better than in many parts of Scotland and Ireland.

The British farmers, however, have the great advantage of perpetual pastures, owing to the mildness of our winters; but still no art of man will shorten the period of animal gestation, and originate a lamb or calf in shorter periods than five months and forty weeks. Evidently does the tradesman or manufacturer turn his capital in that time! There are three varieties of professional farmers, however, who occasionally realise some property: the grazier who feeds with oil-cake, grains, and other artificial foods; the dealer in corn or cattle, who has the art to buy at a falling and sell at a rising market; and the dealer in landed property, who subdivides and sells estates. The profits of the first are not great, and those of the last two are attended with great risk: the only farmer whose lot is to be envied, lives under a landlord who does not take valuable quantities from his estate; such as Burton, Coke, Bedford, Northumberland, and many others in the south; but few in the north, or in the west.
Though agricultural operations, in general, require less nicety as to the exact time of performing them than many of those of gardening, yet there are exceptions in respect to some field crops; for example, beans and turnips. It is proper to observe, therefore, that the almanac time in this Calendar is calculated for the meridian of London; but as a Calendar of nature is given for the metropolitan district, the almanac time may, in every part of the empire, be varied to suit the local climate and vegetation.

In general, other circumstances being alike, four days may be allowed for every degree, or every 70 miles north or south of London; in spring, operations may be commenced earlier in that proportion southwards, and later northwards; but in autumn the reverse, and operations deferred as we advance southwards, and accelerated as we proceed to the north. In every case allowing a due weight to local circumstances.

Our notices under each month extend only to a few of the leading features of countrywork;—to attempt to insert every thing, or even most of the things that require attending to, we conceive impossible; and, if it could be done, quite useless. A man will always act better when guided by his own judgment, than when following implicitly that of another. Calendars should only be considered as remembrancers, never as directories.

#### CALENDARIAL INDEX.

1. **Calendar of Animated Nature round London.**
   
   **In the first week:** whelks笔记and earthworms (Lumbricids terrestres) appear. Second week: redshank (Tringa totanus) white-rumped (Sitta europaea), and whinchat (Saxicola rubetra) white-rumped, and weasels (Mustela alba et lata) appear. Third week: the common lark (Alauda arvensis) congregates. Fourth week: snails (Helix hortensis) and snails (Lymnaea luteola) in the sheltered parts of gardens; the hedge sparrow (Passer montanus) white-rumped, the white tit (Parus ater) widespread, and the blue tit (Cyanistes caeruleus) becoming larger. Fifth week: some plants accidentally in flower; and others, as the Laurens, continued from December.

2. **Calendar of Vegetable Nature round London.**
   
   **In the first week:** some plants accidentally in flower; and others, as the Laurens, continued from December. Second week: winter aconite (Eranthis hyemalis), Christmas rose (Helleborus niger) in flower, and hazel (Corylus avellana) catkins beginning to appear; common hollyhock (Lavatera Periclymenum), tubers begin to appear. Third week: primrose (Primula vulgaris) flowers in sheltered places; daisy (Bellis perennis) and chickweed (Anthemis media) begin to flow. Fourth week: meadow grass (Dactylis glomerata) begins to flow; and sometimes smoky (Symphytum officinale), pansey (Viola tricolor), white scented violet (Viola odorata), archangel (Lamium purpureum), and cress (Cressuapis palustris et odorosa) show blooms. Fifth week: **Furna-yard.**

   **Attend to cattle,** whether in the open yard on straw and a few turnips (411), in hampers for feeding (655), or in stalls (65%). See that the work are not driven from their proper share of green food by the strong; notice any in bad condition, and put them in a place by themselves, and feed them a few weeks. When the hay or straw is of inferior quality or flavor, sprinkle with salt water, which will make it more palatable.

   **Threatening** (31.9°) goes on pretty regularly at this season for the sake of a supply of straw. In some districts it is common to throw an hour each morning by candle-light during the three winter months, the candles being hung up in horizontal. See that the goosebumps and other places are kept oiled, and the teeth of wheels greased or oiled, and coated with antifreeze.

   **Implement:** not now in use may be repaired, also harness grass, chaff, and straw, the mowing and grazing jobs executed, where it is customary to work a part of the winter evenings.

3. **Grass Lands.**
   
   **Dry soils and uplands should alone be stocked with cattle or young horses at this season.** (59.9%) Sheep should not be allowed to graze either on wet or marshy meadows or on young clovers (59.9%). Grass lands under a system of irrigation, may now be kept covered. (58.7%) Dry soils and other places not properly drained shall now have that operation effectually performed on the surface (422.) or under it (452.), according to circumstances.

   **Brown** (70.4%), on some soils do considerable injury to grass.

   **When the label is not considered too much,** and there is a water barrel at any rate, they may be killed by mixing powder of lime with the water, at the rate of one pint to ten gallons. On lawns, and small paddocks, or in the case of feathers and wool, getting rid of worm eggs is an object worth attending to; in this month, February and October, are the best seasons for the operation.

4. **Arable Lands.**
   
   **Plough when the soil is not wet.** Load out dung and farm field dunghills, also compost heaps, with pest or other matters. See that drains, ditches, and watercourses also freely, and answer their respective ends.
Beans (5222.) are in some dry situations planted in the last weeks of December and early January, and sometimes even, as soon. On the whole, however, it is better to defer the beans and peas till the first and second weeks of February, and the oats till the last two weeks of that month.

Beans and the common mustard (400A.) may be sown where the soil is suitable.

7. Peaches (200.), Roads (5232.), and Drains. (4132.)

Peaches may be planted in fence-lines, in any of the different modes. In hedges, hawthorns, and other old fences where the common kind may be formed; but none where hawthorns or other evergreens are to be used. Repair by the different modes. (1897.) Roads and drains may be formed at all times and seasons.

February.

1. Calculated of Animated Nature round London. In the first week: the snowdrop (Galanthus nivalis), whin (Cistus salicifolius), and the herbaceous (Leontodon arvensis), polyanthus (Primula vulgaris) flower; and the sorrel (Rumex acetosa), sorrel (Rumex acetosa), and sorrel (Rumex acetosa) begin to expand their leaves.

Second week: the bunting (Emberiza calandra), and linnets (Flamellus Linnaeus) appear in flocks; the hawthorn (Crataegus monogyna), and the alder (Alnus viridis) begin to flower, and resort to their nest trees; house sparrows (Fringilla domestica) chaf, and begin to huff; the chalk-fringilla (Crinella enlica) begins to flower.

Third week: the partridge (Perdix Perdix) begins to pair, the skylark (Alauda arvensis) whistle, and the wood-lark (Alauda arvensis et albaeaeus) sings; the hen (Phasianus colchicus) sits.

2. Calculated of Vegetable Nature round London. In the first week: the snowdrop (Galanthus nivalis), whin (Cistus salicifolius), and the herbaceous (Leontodon arvensis), polyanthus (Primula vulgaris) flower; and the sorrel (Rumex acetosa), sorrel (Rumex acetosa), and sorrel (Rumex acetosa) begin to expand their leaves.

Second week: the common cowfoot (Rumuncous repens), dandelion (Léontodon taraxacum), and the female flowers of hazel (Corylus Avellana) appear.

Third week: the overall (Festuca pratensis) flowers in flower; many of the poplar and willow tribe show their catkins; and also the seal (Triticapitum), alder (Alnus communis), the birch (Betula), crown imperial (Fritillaria imperialis), and various other bulbs, hardly emerging from the ground.

Fourth week: the wood strawberry (Fragaria vesca), some wood sorrel (Festuca), the gorse, and the ground-burr, the stools and wall-flower (Chelone) flower. Some sorts of goose, geese, and peacocks, beginning to open their buds.

Farmyard. (2002.)

See last month. In taking in stacks to thresh, destroy vermin as much as possible, (6625.) Clear away the bottoming of straw, and other temporary matter, and leave the site perily neat and clean; the poultry will pick up what grain may have dropped. Be vigilant in keeping stack of every description in order; winnowing cattle by frequent supplies of feed, and turnip, or other roots; horses by sound corn, and good straw, or hay-straw, dispension as much as possible with wheat and oat straw. The evening food should, according to the case, be of carrots or potatoes.

Poultry now by freety; and if some indicate a desire to incubate, so much the better where an early brood is an object.

Stocks. The timber is still a good many hours for mental improvement.

Live Stock (9216.)

Sheep generally begin to lamb in this month, and require unwearisome attention from the shepherd. (2112.) As well planted trees as before (1874), and to milk cows (6863) and carting calves. (8435).

3. Roads (5232.), Drains, Ditches (2032.). (4467.)

Hedges may be planted (9278), grown ones pruned (9511), old ones planed or cut down (6627), and imperfect ones repaired. (9511) Walls (8464), water fences and ponds formed. (4167)

4. Orichards (4073), and Hops-gardens. (9397)

Plants which are to be transplanted this month in each tree is practised, this is a good season. Stake and tie newly planted trees as before (1874,). Trench ground for hop plantations. (9067.)

5. Wood-lands and Plantations. (3965)

Prepare the soil for planting. Plant deciduous hard-wooded trees in mid weather. Plant new and the large tree seeds, a better place where they are finally to remain, in nursery-gardens.

Fill smiling and slippery not valuable on account of its bark. Stock trees and hedge trees, and all other trees that are to be sold.

Plant deciduous trees; fill up vacances. Cut hawthorn and bramble in the same month. Cut down wood-lards and cut paths or other openings required through them, the leaves being now off the deciduous trees.

March.

1. Calculated of Animated Nature round London. In the first week: the ring-dove (Calopteryx Padium) cows; the white wattle (Mimosa phans) sing, and the yellow wattle (Mimosa phans) appear. The earthworm (Lepidogaster terrestris), and the small Holice and hag (Lamia enchiophora)

Second week: the chochow (Curvus Mugellii) begins to come to churches; the tootit (Parus carduelis) makes its spring note; brown owls (Strix aluco) hoot; and the small tortoise-shell butterfly (Papilio urticae) appears.

Third week: the marsh titmouse (Parus submaris) begins his note. Various flies (Musca) appear. The foxglove (Digitalis purpurea) blooms well. The turkey-cock (Meleagris Gallo) strut and gobble.

Remarks. The beginning of March usually concludes the winter; and the end of the month is generally indicative of the nature of the weather to come; according to the practice of the weather, which comes in like a lion, and goes out like a lamb. The beginning of this month is the commencement of the growing season to the increasing of the days. This is a laborious and trying month, both for men and cattle engaged in field operations.
Fourth week: the yellowhammer (Emberiza Citrinella) and greenfinch (Chloris chloris) are now appearing in the rushes and hedges and house pigeons (Columba livia) build; the goldfinch (Fringilla Carduelis) sings. Field-cricketts (Scapteriscus) open their holes; and the clock begins to tell time. The idea (Peronema caerulea) appears every day, provided the land is dry enough to be sufficiently cleaned, and pulled up to its full height by a foot. It may frequently happen that this cannot be done until the beginning of April, and hence this class of seeds is sown not before the middle of that month. The carrots should be first sown, and the Beijing turnip will be the last. Lettuce intended for potting, turnips, transplanted Nodding turnips, and other plants of the Fruticose kind should be brought forward by such ploughings, cross ploughings, and working with the grubber, as their nature and state may require. It is one great advantage of the common kind of turnip, that it admits of two months more time for preparing the soil than other root or Fruticose crops, and the seed should therefore require at least one furrow in course of the month.

5. Fences (1600). Roads (3523), and Drains (1413.). Thorns and other hedge plants may be put in, but the earlier in the month the better. You may in this week set out with an excellent season for making or repairing roads (3527.), grains, roots, potatoes, beans, &c., the ground being still moist; and the days sufficiently long to admit of a man's labouring ten hours, or more. In fact, when no wind prevails, it is frequently possible to finish putting in deciduous trees with the month; using the cuttings for improving certain breeds of the grey and white kinds. Where large trees are introduced, the latter generally require to be staked.

6. Wood-trees and plantations (3506.). In the tree nursery, finish sowing acorns, keys, mats, hawthorns, and other nursery trees. Be especially careful with the walnut (where it can be got), willow, birch, elder, elm, &c. Transplant from the nursery to the field, and from the field to the nursery, and attend to other parts of the usual routine culture. New plantations, or the replanting of old ones, if possible, may be finished, in deciduous trees with the month; using the cuttings for improving those breeds of the grey and white kinds. Where large trees are introduced, the latter generally require to be staked.

7. Orchard (4875.) and Hop Grounds. (5097.) Finish pruning fruit-trees (5011.), and also diggig round their stems, limbs, &c. With a pick, the earth should be removed to the top to two or three inches, and the roots and branches of the tree, and all roots and branches which are gross, see that the guards or fences to the single trees are in repair.

8. Formations of hops (5051.), and open up and dress the fields of established plants, returning the mould to their roots. (5065.)

A careful, not very lenient, round of pruning is highly recommended in near the end of this week, as well as in the middle of the month. If any of the trees, especially the larger ones, have not been pruned with the greatest care, they should be cut down to the earth as far as may be necessary, and the tops of the branches carefully reduced. If the trees are not properly pruned, they will remain in a state of disorder, and will not then bear fruit in abundance, but will, on the contrary, produce a great deal of young wood and branches, which will grow and develop themselves without any regard to the form of the tree. It is therefore necessary to prune carefully, and to cut down to the earth as far as may be necessary, the tops of the branches, and to remove the branches and twigs which have grown in disorder, and which are not likely to bear fruit. If any of the trees, especially the larger ones, have not been pruned with the greatest care, they should be cut down to the earth as far as may be necessary, and the tops of the branches carefully reduced.
CALENDARIAL INDEX.

Where there are water-meadows, the sheep and lambs will have been fattening on these during the whole of the month, an immense advantage to a farmer.

Petroleum and pitch are generally cleared of dung, urine, &c., at this season; and if no sewage goes on, they should be kept clean during the summer, excepting what room is required for the dung of the few stock which are there constantly, as pigs and poultry, or occasionally, as horses while harrowing, &c.

In the first week: the titlark (Amaura fenestrella) sings, the cuckoo (Cuculus canorus) is heard, the guinea (Cynops cyanurus) appears, and the swift (Apus apus), white-throat (Motacilla alba), and ringling-tye (Oxyptila citrinella) appear.

Second week: the pastures are torrid: Colomera Turtur cost; the red ant (Formica rubra), the laughing wren (Motacilla CURRA), the black ant (Formica onusta), the black-tailed ant (Formica nigripilis), grass hopper bark (Anaxia Locustula virid), and white ant (Formica alpina) appear.

Third week: the black fly (Musca coriaria) appears; black moth (Helix nigra) appears; and the large bat appears.

Fourth week: the great white-cabbage butterfly (Papilio brassicae) and dragon fly (Libelloidea 4-maculata) appear; the glow-worms shine, and the fireworms, or gest-waterer (Lampyridae europeaeus), return.

2. Calendar of Vegetable Nature round London.

In the first and second weeks, the buttercup (Ranunculus), bell-flower (Campanula), and lily of the valley (Convallaria majalis), water violet (Viola Palustris), tulpine (Lilium Candidum tulipifer), and numerous other plants in flower, are blooming in great profusion, with various Maculata, and various Anemone sharps, and on the fields alike (Lampyridae europeaeus), return.

3. Farm-yard. (5022.)

Feeding and winning on straw and roots generally ends, and the sow is likely to be seeking for pastures (5524.), or patches (5525.), in the first fortnight. Where high-flavored milk and butter are better in quality, than pastures on dry ground, where the quality and richness is the object, milking with care and tares, and two or three hours pasture, per day, for the sake of exercise, is the preferable system. Even on farms where there is nothing to move but old meadow, sow and stock will have been more economical than pastures, &c. A field of meadow in good heart, mown and eaten green, will, at a rough estimate, produce the quantity of milk it would have done if pastured, and four times as much as it would do in the form of dry hay.

4. Form-yard. (5022.)

Vegetation now goes on with great vigour, though there are often very cold and even frosty nights, which materially injure the blossoms of fruit trees, and sometimes even the blossoms of the hop and potato. Man, in common with other animals, being now full of life and consumption of animal destruction, and particularly of marriage, and business is better deferred till September, when the conditions will be more favorable to both. There is no danger of the grass, in small beds or rock, than in large ones. Horses may have the horse during the first week, but not later considering the season of pestilence (5025.).

5. Grass Lands. (5043.)

As most grains send up their flower-stalks during this month, it is of importance to stock pastures, as to cut these down. This is only to be accomplished by in recently sown down lands to be overstocked, and not too completely if dry grass prevail. When grass lands are to be mown, the best crop of hay will be obtained by not pasturing after the middle of April. Some plants, such as clover and rape are fed till May or June, the stalks left will come in as hay; but as such fields are usually cut with the hay, the hay must be cut before the seed is ripe, and dry straw to be used as feed for cattle and sheep are very numerous, they are found to fed better, and do less injury to the grass, in small beds or rock, than in large ones.

When pasturing and burning are wanted, this is a favourable season. (5025.)

6. Arable Lands. (4925.)

Summer wheat (5301.) and grass seed (5573.) may still be sown, but should be followed by the first week of ten days or two weeks; after spring (5497.), maygrass, and yellow turps may be profitably sown, and also early crops of common white turnips, which may be sown in the same manner as above.

The preparation of farrow寄托 is the greatest business of this month, the continuous feeding of good pastures, especially culture, by horse and hand hoes, of corns and pulse in drills. In London, the sow should be ready for farrowing in the last week of the month (5316.); and hemp and flax down in the first fortnight (5850. and 5922.) for successional supply (5627.).

7. Fences (5292.), Roads (5322.), and Drains. (5413.)

Clean young hedge-rows. (5325.) Drains now may be advantageously designed, as the ground shows itself more coarse and porous. The rest in this department is very routine.
8. Orchards (4679.) and Hop-grounds. (5907.)

Grass trees should be looked over occasionally, and any that the cow apes to eat from roots. Remove suckers also from other

In the first week: the solzosparax (Passer amandineae), the fly-catcher (Muscicapa Arundinacea), the wisp (Fesa vulgaris), and several species of the bee and butterfly appear.

Second week: the burnet moth (Sphinx hampdenella), and blue-bottle (Calliphora vomitoria) appear.

Third week: several flies, butterflies, moths, beetles, and other insects appear.

Fourth week: insects abound; and singing-birds begin to retire to the woods, and leave off singing.

2. Calendar of Vegetable Nature round London.

In the first week: water-lilies (Nymphaea et Nuphar) flower; also Iris pseudacorus, Anthericum liliaceum, Polygonum Persicaria, and several fresh and tender plants.

Second week: the blue, raspberry, and elder in full flower; also borax rod, cowslip (Primula veris), and scorpion (Urtica), and wheat in the ear.

Third week: the Orchis, Erythraea, Pity Phosphorus, and spider, is a great variety of garden and field plants in flower; also the wheat and many of the pumpkins.

Fourth week: some black and red currants ripe, strawberies in abundance; young shoots of trees and shrubs have sometimes attained their length. Oats and barley in flower; bluebottle, scabiosa (Scabiosa Cyana), and numerous others in blossom.

4. Live Stock. (4265.)

Wash and shear sheep (7201.); examine flocks individually as to the fly (1715.); see to shoe for every description of stock when the weather is hot. Bees swarm during this and next month.

5. Grass Lands. (5648.)

Hay-making is now a great social business (5641. and 5792.) Any tassoe or flower-stalks (bents) which appear, notwithstanding the close feeding of April and May, should now be mown (5641.), and small and similar weeds cut out close by the root (4679.); bare and turn as in May (5649.); clean out ponds, water-courses, wells, &c. See that clovers, vaters, or other soil inging crops are now close to the soil.

6. Arable Lands. (4925.)

Great part of the turnip process goes on during the three first weeks of this month and the latter part of this, (6537.) Dung fellows and otherwise bring them forward (6535.), draining (6531.), and cutting (6515.); and if they are very thick require; weed, broad-cast crops, and stir the soil between such as are in rows. Warming, where, which can be continued, is now out the first sowing turnips. (5946.)

7. Fences (3080.), Roads (3023.), and Drains. (4135.)

Dug and otherwise prepare materials for roads (5635.) and drains, (4284.)

8. Orchards (4679.) and Hop-grounds. (5907.)

I.uts, or other effects of what are called blights, can seldom be destroyed; but may be preserved in the form of the farm-yard or hop-garden. Burning weeds or wet straw, litter, &c. or will do something; or with a small fire, whaling the new green food will be as effective. In the middle of the month, for the sake of the pole, instead of leaving them to nature, have generally completed the operation by the middle of the month, the superficial shon is cut off about the early spots of the second week; the shoo imprisonment is cut off about the early spots of the month.

9. Wood-lands and Plantations. (5906.)

The wood is now chiefly employed in turning up the branches of trimmed trees, and otherwise disposing of what is unfit for timbers (4015.) Old crops of stooks of trees, or hedges may now be adventurously stocked up, stacked, and when dry, charred for fuel. (4068.)

JULY.

In the first week: the cow parsley (Curculio camara) leaves off singing; the stone-carvel (Charidium eucharum) whiskies occasionally over the garden with the golden crested worm (Myxocella Rubricola) now and then chips.

Second week: the cockerel (Gallus gallus), and the cock-a-spills, (some cock-a-spills (Gallus spurius), and aunts.

Third week: young frogs migrate. (5929.)

Fourth week: the great bumble-fly (Tabanous levius) appears; and partridges fly.

2. Calendar of Vegetable Nature round London.

In the first week: enchanter’s nightshade (Girseis hyacinthus) and lavender (Lavandula spica) in flower, and pinks and currants in full bloom.

Second week: the fallen star (Teumella Notata) appears; also pot-bellied (Lysosoma Berolinum), and several other species of autumnal flowers.

Fourth week: the truble (Tuber Aauratum) now haunted or dug up, and forest and forest nightshade (Solomonagram), devil’s bit (Scrophularia scrofulosa), barberry saxifrage, (Pimpinella saxifraga), and the number of plants in flower decreased.

3. Farm-yard. (5920.)

In June: between hay and corn harvest is generally a very good time for the farmer to make a tour to observe more especially the practices of his own district, and to witness those of other districts.

Rain. 

the stool or centre of the plant with a small hill of soil, to prevent it from sending up more shoots.

3. Wood-lands and Plantations. (5906.)

Continue to plant trees, young Walnut, and Christ Church, and such others as are adapted for the farmer (4945.), but finish, if possible, by the middle of the month. Keep new planted trees properly staked, and all kinds of cultivated ground clear of weeds.

JUNE.

Remarks.

The weather is sometimes cold at the beginning, but is generally agreeable and steady towards the middle of the month. By observing the columns indicating the greatest variation of the thermomeeter in each month, it will be seen that it varies, in London, only two degrees in June, which is less than any of the preceding months. In July and August the variation is the same; but in March and October it is twice as much.

 websocket/ll"
and other places these pruning are often a perquisite of the pruner, who lays them aside for fodder. 9. Wood-lands and Plantations. (3963.)

**AUGUST.**

1. Calendar of Animated Nature round London. In the first week: lying out (Fornix) appear; bees kill their drones; and the swallow-tailed butterfly (Papilio Machao) appear. Second week: young martins ( Hirundo urbica) and swallows ( Hirundo rustica), begin to congregate, and swiftly ( Hirundo . fuga) to depart; the whame, or burrow-bird (Oeisuru lawis), lays eggs on horses.

Third week: the black-eyed marble butterfly (Papilio Scicle) appears. Various birds re-assume their spring notes. Fourth week: young oaks ( Fagus sylvatica), greyhounds (Canis familiaris) whistle at night, the great crested grebe (Podiceps cristatus) and young blackbird (Sturnus Vulgaris) make noise in the evening; robin-redbreast (Monticola fusca) sings; and rooks roost on their next-trees.

2. Calendar of Vegetable Nature round London. In the first week: mid-leaf (Trifolium officinale), rue (Ruta graveolens), yellow sorrel (Rumex hirtellus), burdock (Arctium minus) in flower; the broad-corn (Fagopyrum).

Second week: wild cary (Salvia farinacea), meadow-ruce (Thalictrum fucifolium), yarrow (Achillea millefolium), and various other natives in flower.

Third week: the shallot (Allium schoenoprasum), hollyhock (Alcea rosea), and lobelia, among the garden-flowers; and the polyanthus and potamogenthes among the wild plants now in blossom.

Fourth week: the autumn cress (Cardamine annua), August Stock. Soothing pleasant, of which have been called (Parnassus aellus), and various other plants in flower. The earlier varieties of all the hardy annual fruits ripe.

3. Fowlers-gar (3962.)

The rockyard shall now be attended to (3966); stocks, stakes repaired or put in order; bottoming of eggs, and straw or rape had not got together; trash in readiness, and ropes made. (3984.) At any spare period the teams may be employed cutting out the somets made dung to the wheels follows, or to form field bedding for young crops.

4. Live Stock. (3216.)

Select the stock of lands to be kept as breeders. (3760) Sow carefully, and their most native character, which, owing to the dressing corn, is generally one of abundant keep, both for them and poultry. Farmers in some places look to the stubbles as a source of good food for their cows, as

5. Grass Lands. (5613.)

Where swine are managed, that operation generally goes on after the hay is removed, or during winter; the surface in the former case being hard with drought, and in the latter by frost. After grass should in general be shut up and reserved for later keep, and in some cases as a winter resource. Keepdown woods, tussocks, ant-hills, etc. Turn the water on meadow-lands and grass crops. The heavy rain and let it remain till a third crop is in forwardness. (3585.)

6. Arable Lands. (4925.)

Wet and bottomless gravelly crops, earth up potatoes (5556), but by no means turnips, unless the soil is very dry indeed, as this operation only prevents them from attaining a full size. Helpful commences in all the southern districts in the first week of this month, and in some by the middle of July. When the operation is hectated by day work, mowing, and most important inspection of the master is necessary; and even when the greatly preferable mode of requiring a splendid class is adopted, he should be continually in motion from one party to another, to see that the operations are well performed and low.

Naked followers in late situations receive the seed furrow during this month, erecting in cases where the seed is ploughed in, or as near the gravelly soils derived to the middle of September. Sew cabbage-seeds (4497) for plants to put out in April next. Now rising crops of peas and beans which have been called (Pisum sativum), or early cut wheat, fairs, cabbages, etc., or after hemp and flax, which are generally pulled by the middle of this month. (5805. and 5925.)

Grass seeds sow alone at this season (5692) will generally succeed better than at any other; they germinate as well in spring; but the heats of July often burn up the tender plants.

7. Fences (2000.), Roads (5223.), and Drains. (4913.)

As in the two preceding months.

8. Orchards (4569.)

And Grove-lands. (3927.)

Apples becoming ripe, and their most native character, which, owing to the dressing corn, is generally one of abundant keep, both for them and poultry. Farmers in some places look to the stubbles as a source of good food for their cows, as

9. Wood-lands and Plantations. (3906.)

See last month.

**SEPTEMBER.**

1. Calendar of Animated Nature round London. In the first week: young brooks of goldfinches (Fringilla Carduelis) appear. The limet (Fringilla Lintsa) congregates. The bull. This Tarus) makes his shrill autumnal noise; and swallows ( Hirundo rusticula) in flight.

Second week: the ring surroundings ( Turdus montanus) appear. The flycatcher (Syrina meerry) and bluetit (Parus afer) withunter. Fourth week: the starling. (Sturnus vulgaris) congregates. The wood pigeon ( Cuculus) is heard. The curlew (Numenius stuartus) and teal (Anas platyrhynchos) appear; and the swallow ( Hirundo rustica) departs.

2. Calendar of Vegetable Nature round London. In the first week: some turnips and Batatas dilatata appear, a treacle's joy (Trachesta Dula) and Phacelia galactica in flower.

Second week: cottons of the horn and for it formed blossoms, and green, red, and black berries found on the bramble at the same time. Leaves of the sycamore. birch. lime, mountainash and elm, begin to change colour.

Third week: the ivy (Hedera Helix), laurel (Prunus Laurocum) and fustic (Ceylon eurinag) in flower.

Fourth week: hips, haws, and nuts ripe. Leaves of plane-tree (Platanus tannus); of the hazel, yellow; of the oak, yellowish-green; of the sycamore, dirty brown; of the maple, pale yellow at the same time last; of the elm, orange; of the hawthorn, tawny yellow; of the cherry, red; of the hawthorn, bright yellow; of the willow, hoary.

3. Farm-yard. (3902.)

The rich and luscious abundance of fat cattle and sheep in the market during this and next month. Lean stock, especially cows and calves, are now brought in and winter. Fed or fed on turnips. Wintering cattle (6553.) about the end of the month. Poultry and pigs are now fat, and honey may be taken from bees.

4. Livestock. (6613.)

As in August. Newly sown grass lands should now be freshly fat, in order to strengthen the plants for the winter.
6. Arable Lands. (4925.)

This is the chief season for sowing winter wheat, whether on naked fallows, or after clover, tares, rape, or other leguminous crops and beets. potatoes are generally not taken up till the end of the month, in case the sowing after first crop is later. (4925.) The rest of the month is generally set aside for permanent pasture; or a hay crop next season will succeed on these soils, it is known before the middle of the month. (4552.)

7. Fences (3904), Roads (3233), and Drains. (4123)

Routine operations of mending, &c. as before.

8. Orchards (4575) and Hop-grounds. (5697)

Gather fruits for immediate sale, the keeping sorts not being yet ripe. (4695.) Walnuts for picking not later than the first week. (1110.)

Hop-picking and drying, in the districts where this plant is much cultivated, is the great business of the month. (5697.)

9. Wood-lands and Plantations. (2066)

Routine operations as in the two or three preceding months. Plant evergreens during the three last weeks, and deciduous trees the last ten days. (5697.)

OCTOBER.

Remarks.

The weather of this month is very uncertain. Before these rains, snow, or frosts which constitute the practical commencement of winter, there is only the month of October. The weather of the last three weeks settled weather; sometimes these weeks are far colder than in October, sometimes positively very mild. These weeks afford a last resource for bringing forward neglected operations.

5. Grass Lands. (5613)

Where these are managed, this is a good season for the operation (5613.) choose dry weather.

6. Arable Lands. (5725)

Potatoes (5613.), carrots (5141.), field beet (4531.), parsnips (5471.), and Swedish turnips, may now be taken up and housed, and the ground sown with wheat. This crop (4531.), rye (5459.), oats (5695.), peas (5697.), beans (5697.), and others may still be sown in the market districts. Turnips every opportunity to give the first harvest of turnips (4531.), whether for green crops or otherwise. In general all lands that are to be worked in the course of the field, are to be sown after the first crop, should be ploughed as soon as possible after harvest; but not so lands that are to be sown for green crops, which are better ploughed in January and February. It is a great mistake to suppose that the sprouted land is in good condition for autumn crops. Be careful to distinguish between these two varieties of a host of insects (5695.), the seeds of which are very destructive, from being devoured by birds. There are few subjects less generally understood than the economy of nature in regard to the eggs of insects and worms. (Turn to 4764. and 7701.) Notice that water furrows and drains run freely, and that fences and gates are in repair.

7. Fences (3904), Roads (3233), and Drains. (4125)

Hedges may now be advantageously planted (5695.), grown ones pruned (4695.), old ones ploughed (4531.), and imperfect ones replanted (4695.) The Northern number of evergreens, as to hedges (5697.), well deserves the study of the more southern agriculturist. Roads and drains may be made or repaired, with better effect than during the heat and drought of summer. Road materials now bind better, and improve more slowly than in other months.

8. Orchards (4575) and Hop-grounds. (5697)

The winter fruits may now be gathered, and either spread in a dry room or on an upper floor, there to remain till used, or wineticed in heaps, to extract a part of their moisture, and then buried in dry sand, or packed in close boxes or sacks, to be kept as cool and dry as possible. (4575., and 7704.)

Fruits and berries of every kind may now be planted (4695.) and pruned. (4111.)

Hop-picking is generally completed the first week of the month; and as soon afterwards as convenient, the vine and vines restored, and the late young shoots pruned, till next spring. (4695.) Young hop plants may be furnished (4695.), and the soil among established grounds manured and ploughed. (4695.)

9. Wood-lands and Plantations. (2066)

Hedges and borders of evergreen trees may now be pruned during the first week of the month; and no period of the year is better for transplanting all kinds of trees, holly, poplar, sycamore, mulberries, vines, maples, elms, oaks, and others, than October. The cutting of timber and coppice may then be taken up, and in general every operation preparatory to planting, as well as the operation itself, may go forward.

NOVEMBER.

Remarks.

This is the rainy month of the Saxons: it is generally the coldest month, and one of the most disagreeable for the labouring agriculturist; but he can console himself with the expectation of a fine day, and hope of even weather, when he may lay aside his wet dress and cloths, and enjoy his mind by converse with books, or enjoy the comforts of the fire-side, or the solids of the table, with the children reading to or otherwise instructing them, or mending his tools or shoes.

Weather at London, Edinburgh, Dublin:

Dublin 184 184 207 234

4 A 4
December.

   The mole (‘Pipis europaeus’) throws up molehills. The December moth (Eilegomeris pupalis Sama) appears about the beginning, and the yellow-line quaker (Chaetognatha Sama) about the end of the month.

2. Calendar of Vegetable Nature round London. 
   Some of the last month’s plants continue in flower, according to the weather.

3. Live Stock. (6216.) 
   Trenching, and otherwise preparing corn and straw for the market, and the use of the working, fattening, wintering, and store stock are the main operations. Next, the regular supply of live stock with food, and cleaning and littering them. Feeding stock should be particularly attended to, especially hound stock (7827.) and calves (8255.).

4. Fences. (2906.), Roads. (3523.), and Drains. (4212.)
   Trenching and other operations of the last month, where interrupted, deferred, or neglected.

5. Grass Lands. (5938.)
   Mauve in dry weather (5838.); turn the water on meadows alternately. The rose, the primrose, and the winter savory are useful as water repellents for the sheep. Sharks and the cattle and horses only on the driest pastures; see that sheep have shelter, and especially Durnett even likely to lamb next month.

6. Arboreal Lands. (4925.)
   See that water furrows and drains run unobstructed; plough and cart out mauls, as weather and other circumstances permit.

7. Fences. (2906.), Roads. (3523.), and Drains. (4212.)
   As in last month; and see that they are in effective repair, and fairly used.

8. Orchards (4079.) and Hop-grounds. (5997.)
   Complete the operations of last month, where interrupted, deferred, or neglected.

9. Wood-lands and Plantations. (5026.)
   As in last month, excepting when the weather is unsavourable, and all kinds of work, success, yet one season has a preference over the others with me; and when there is the power of choice, I would recommend late in autumn, winter, or early in spring; that is, any time from the middle of October to the middle of February, and in general the beginning of this period is the best; that is, from the middle of October to the middle of December, always providing that the weather and the ground are favourable; that is, suppose there is no frost, no drying wind, nor much sunshine, and that the ground is not too much saturated with either from continued rain, or from the nature of the soil. One of the principal things to be attended to in planting evergreens is, to fix on a dull day for wintering, and to allow the time for planting. There can be no secret in the proper treatment of evergreens, and I should say, that it is in preventing their roots becoming dry when out of the earth; to choose a bed of soil with proper soil for planting; and see that the same soil, or that we had the power, by foresight or otherwise, to secure a con- tinuous water supply, either some other time after they have been planted. (M’Nab’s Hints on the Planting and General Treatment of Hardy Evergreens in the Climate of Scotland, Ed., p. 17.)

Mr. Crabbs has shown that poor waste ground, which, if trenched or ploughed would not bear a crop of grain, will, after being ploughed and kept under wood for some years, become fit for every purpose of agriculture. ‘On a rising ground, not far from the village of Kilnot, a piece of ground of a dry gravelly nature, which has lately been cleared of a crop of full-grown Scotch iris, was trenched in a very partial and imperfect manner, and the roots of the iris being so eerily eradicated. It was then sown with oats, without receiving lime, dung, or manure of any kind; yet the result was so luxuriant, that a great part of it is lorded. The following spring, the grasses have completely grown up and slain the scars, without receiving any enriching; and, when harvest ar- rived, the crop was unseasoned by that of the heather fields, which is generally called ‘barley-meal.’ The experiment was tried a third time, still without manure, and the crops was again considerably above an average. The soil, as it has already been remarked, was dry and gravelly, and for such crops again considerably above an average. When the weather is not proper, it has been covered with heath, and in such state that had not been able.3. The waste lands which may be commonly seen improved at a vast expense, and which will produce no kind of crop, I conceive a great quantity of manure.” (Crabbs’s Practical Planter, Ed.)
Glossarial Index.

In this index both Pages and Paragraphs are referred to ; the letter p. is prefixed to the former, to the latter the letter a.

A R R I N G E D earth, earth crumbling down from the effects of frost, page 483.
Absorbent soil, soil so constituted as to absorb moisture from the atmosphere, 712.
Absorbtion system, explained in s. 6339, p. 908.
Acclimatising vegetables or animals, inuring them to a climate in which they are not indigenous. The term naturalising is sometimes substituted, but erroneously. See Naturalising.
Ascendent, entering a state of acid fermentation, s. 6978, p. 1056.
Aeration, exposing the soil to the air, p. 507.
Aereometric beads, hollow beads of glass containing air, for ascertaining the specific gravity of milk, s. 7038, p. 1092.
After-grass, the second crop of grass from lands which have been previously mowed the same year, p. 903.
Aer, the second mowing of perennial meadow lands in the same season, p. 515.
Agriculture is used in its most extensive sense in the third line of the title page, and generally in the historical part of the work (Part 1), as including territorial economy and husbandry. In most parts of this work, for example, in the wordings of the title-page, "animal and vegetable productions of agriculture," as synonymous with husbandry. In several places as synonymous with aratition, that is, the culture of arable lands, as opposed to pastureage, or what may be called agriculture proper. In every case the reader will be able to gather, from the scope of the sentence or paragraph containing this term, in which of these three senses it is meant to be understood.
Aigrettes, plumes of the stork, p. 1088.
Aigret, a large black cock of the crane, p. 1060.
Alburnum, a type of water-meadow, p. 353.
Alburnous. See Alburnum.
Alloedially, in a different manner, p. 1468.
Aloetic, exposed to frost and thus induced, p. 646.
Amenities, acres of arable land, p. 6978.
Amen, the heads or long bristles which project from the chiefs; they are plentiful on spring wheat, and on barley, p. 812.
Antler, the principal root of the air, p. 814.

B

Backing a horse, explained, s. 6657, p. 1000.
Back-raking, an operation in fertry, by which hardened faces are withdrawn from the rectum, s. 6543, p. 999.
Back-rents, rents paid subsequently to reaping, p. 768.
Bagging, explained, s. 5173, p. 575.
Baits, a substitute for fixed standings or stall, s. 1003, p. 1084.
Band-win ridges, ridges formed of such a width as to be reaped by what in Scotland is called a band of sheavers or repears, s. 990, p. 526.
Beds, explained, s. 6852, p. 597.
Bastard-cocks, small preparatory hens, s. 5797, p. 504.
Battering, as applied to fences, leaning inward, s. 4394, p. 754.
Beds, in Scotland, ground left unturned between the furrows, ices in ploughing, p. 711, in England the same thing, and also strips of ground usually in grass between ploughed ridges, as in common field lands.
Bows, brush-faggots, s. 5939, p. 584.
Bear, an iron instrument used in the Isle of Ely to eradicate weeds in water-courses, s. 5666, p. 892.
Beans, the dead stems of grass in pasture grounds which have borne seeds.
Biggs, a variety of winter barley, s. 5635, p. 882.
Billet, a term variously employed. A wooden billet is often used in docking a horse, and often forms a separation between carriage horses, s. 6575, p. 1000.
Bolting and stockling, binding sheaves of corn, and placing them in shocks or stooks, s. 5175, p. 315.
Bonet, a variety of double mould-boarding plough, s. 2520, p. 592.
Breach holding, a mode of legal tenure in Scotland, s. 3401, p. 552.
Blaze, a disease in the stomach of sheep and oxen from wind; also a term for the mildew in wheat, p. 1065.
Blinding, filling up interstices between stones on roads with gravel, s. 3654, p. 589.
Blood spars in horses, 961.
Blowing lands, lands whose surface soil is so light as to be liable, when dry, to be blown away by the wind, p. 570.
Blowing sand, p. 749.
See Blowing lands.
Bolus of ears, the trunks of trees, p. 650.
Bolt, a measure for corn in Scotland; in wheat and beans, equivalent to four Winchester bushels; in oats, barley, and potatoes, to six bushels, p. 542.
Bone spars, explained, s. 6157, p. 986.
Boulder stones, large round stones, p. 481.

horse with a sensitive mouth has a good appui, and the same may be said of the rider if his hand be good, s. 6965, p. 1092.
Acinous humour, the watery humour of the eye; the first or outermost, and thinnest of its three humors, p. 970.
Aratlon, ploughing or tillage, s. 3562, p. 573.
Aervianous grasses, grasses suitable for sandy soils, p. 749.
Accearunator, a pruning instrument, consisting of two blades fixed on the end of a rod, acting like scissors, by means of a line fixed to one of them, and pulled by the operator, s. 5153, p. 512.
Arora, the heads or long bristles which project from the chiefs; they are plentiful on spring wheat, and on barley, p. 812.
Arteries, explained, s. 6344, p. 597.
Arbor, the radical principle of the atmospheric air, p. 814.
C.  
Cadence, as applied to horsemanship, a measured or proportionate motion observed by a horse in all his actions; and even he, if well managed, and works justly at a gallop, terra a terra, so that his motions or times have an equal regard to each other, s. 8675. p. 1063. See Crabb's Technological Dictionary.

Cassions, temporary cisterns in which foundations in deep water are built, s. 4337. p. 718.

Catecvosol, soil abounding with lime, s. 775.

Calthers, or callifers, explained, s. 4753. p. 663.

Calciferos, from color, heat, and ferc, to bear, explained, s. 7404. p. 1057.

Camping potatoes, explained, s. 5343. p. 561.

Cannon, or horse, explained, s. 6232. p. 959.

Cantle, the protuberant part of the saddle behind, s. 2475. p. 1063.

Capillaries, the hair-like extremities of the arteries and veins, s. 6352. p. 988.

Cap of straw, explained, s. 3185. p. 518.

Capillary, or ides made in one and the same place without advancing forward, s. 6674. p. 1603. See Crabb's Tech. Dict.

Capillary, explained, s. 6125. p. 997.

Carotis arteries, two principal arteries which carry the blood to the head, s. 6388. p. 972.

Carots, 907. See Caneots arteries.

Carrot, explained, s. 6317. p. 863.

Carriage in irrigation, explained, s. 4498. p. 728.

Cary, explained, s. 4354. p. 747.

Caraway, or licourcy, explained, s. 6370. p. 970.

Cassowan, of the nature of cheese, s. 6679. p. 1066.

Cassiate, to incapacitate male animals from engendering offspring, s. 7361. p. 1009. See Spay.

Catch-drain, explained, s. 4419. p. 727.

Catch-work meadows, explained, s. 4438. p. 727.

Cassowaries, a sort of fowl, either of iron, heather, or golden color, from round the nose of a large to forward the suppling and breaking of the horse, s. 6657. p. 1061. See Crabb's Tech. Dict.

Cereals, an important membrane in animals in which the fat is lodged, s. 783.

Cereal grasses, the kinds producing corn, s. 723.

Cereal lupins, explained, s. 7267. 7268. p. 1461.

Cereals, or grain, grown in a strong band, age of packwax, which runs along the neck and supports the head, s. 975.

Cerebrum, a kind of horse waship used in riding houses, s. 6662. p. 1061.

Clear wood, to, to partially burn it to enable it to resist wet, s. 309. p. 452.

Clearlock, the, a wild species of the mustard family, s. 950.

Chloride of calcium, quicklime, s. 4988. p. 510.

Chops, a milky fluid secreted from the aliments in the stomach, s. 604A. p. 1.

Cicatricial, to heal over with a scar, s. 513.

Cilla, cyclanches, s. 970.

Cilium, or cilia, s. 7248. p. 1665.

Climes, cramps or half-fastens; to clench, to turn the points of nails which have been driven, as in the shoeing of horses, s. 6710. p. 1007.

Clow, explained, s. 4455. p. 722.

Cob, a kind of wicker basket, made so as to be car- ried on the arm; hence a seed-cob, or seed-lip, is a wicker basket or carriage attached to the saddle, and hooked on the shafts, which enables him to push back the cart or other machine to which he is harnessed.

Coffin in the true, or in the same line, explained, s. 561.

Coffin in and in, explained, s. 561.

Coffin, cros, explained, s. 561.

Coffin ridge, a quarter-clerf rod, as thick as the finger, and four feet in length, used in thatching, s. 518.

Colin, a Scotch dish made by pouring boiling water on oatmeal, and sometimes on the meal of peas, and immediately mixing them by stirring; leaving the meal in small knots or lumps about the size of marbles. It is afterwards eaten with milk or butter, s. 5217. p. 857.

Collage-holding, explained, s. 5304. p. 559.

Collar and ridge, or ridge rounded ridges, short irregularly shaped lands or ridges in the corners of fields, s. 9533. p. 527.

Cory, cow-sheathed, s. 6777. p. 1015.

Chloride of calcium, quicklime, s. 4988. p. 510.

Chops, a milky fluid secreted from the aliments in the stomach, s. 604A. p. 1.

Cicatricial, to heal over with a scar, s. 513.

Cilla, cyclanches, s. 970.

Cilium, or cilia, s. 7248. p. 1665.

Climes, cramps or half-fastens; to clench, to turn the points of nails which have been driven, as in the shoeing of horses, s. 6710. p. 1007.

Clow, explained, s. 4455. p. 722.

Cob, a kind of wicker basket, made so as to be car- ried on the arm; hence a seed-cob, or seed-lip, is a wicker basket or carriage attached to the saddle, and hooked on the shafts, which enables him to push back the cart or other machine to which he is harnessed.

Coffin in the true, or in the same line, explained, s. 561.

Coffin in and in, explained, s. 561.

Coffin, cros, explained, s. 561.

Coffin ridge, a quarter-clerf rod, as thick as the finger, and four feet in length, used in thatching, s. 518.

Colin, a Scotch dish made by pouring boiling water on oatmeal, and sometimes on the meal of peas, and immediately mixing them by stirring; leaving the meal in small knots or lumps about the size of marbles. It is afterwards eaten with milk or butter, s. 5217. p. 857.

Collage-holding, explained, s. 5304. p. 559.

Collar and ridge, or ridge rounded ridges, short irregularly shaped lands or ridges in the corners of fields, s. 9533. p. 527.

Cory, cow-sheathed, s. 6777. p. 1015.

Chloride of calcium, quicklime, s. 4988. p. 510.

Chops, a milky fluid secreted from the aliments in the stomach, s. 604A. p. 1.
in contradiction of work done and paid for by the measure of time, p. 976.

Pigeon-cot, explained, s. 7541. p. 1036.

Piggery, the compartment in a farm-yard, with sties and such other accommodations allotted to pigs.

Pile, the shag or hair on the skin of animals. Each hair may be called a pyle, s. 7143. p. 1032.

Pillow-flip, pillow-case, p. 1040.

Pining, explained, s. 7253. p. 1055.

Plating, s. 7591. p. 1065.

Plow, explained, s. 7523. p. 1065.

Podders, persons employed to collect the green pods of peas off the plants, p. 837.

Polled, salt marshes in Holland and Flanders, p. 774.

Pole-cow, or poll cow, a disease of the polled or horn, usually at its hind part, or in the nape of the neck, s. 5411. p. 988.

Pooled, hornless, devoid of horns, s. 6786. p. 1016.

Pomace, the pulp my mixture which apples are reduced by grinding in the cider counties, preparatory to pressing out the juice, s. 6757.

Pommet, the prominence in the front or fore part of a saddle, p. 1003.

Potato pies, explained, s. 5144. p. 851.

Pouter, a variety of pigeon remarkable for its habit of pouting, p. 1019.

Preventive pruning, explained, s. 5299. p. 649.

Prestige, the flexible piece of whalebone with a sponge fixed to the end, used occasionally in probings the throat, s. 6653. p. 1032.

Puddling, explained, s. 6620.

Pulls, half, or detached parts of a read, requiring extra pulling in draught animals, s. 3277. p. 922.

Pulmonary artery, explained, s. 6243. p. 967.

Punish, the coin or consistence of a politic or of a piece of iron, p. 1057.

Punished foot, explained, s. 6251. p. 957.

Pincia lachrymilia, explained, s. 6759. p. 970.

Pupa, the chrysalis state of insects, p. 1112.

Purchase of the bride, the command or control of it, s. 6676. p. 1093.

Purinose, purinosus, shortness of breath, s. 6963. p. 1093.

Pyrges, firestone, s. 5228. p. 523.

Pyrogogous acid, acid produced by distillation of the spray of trees, p. 483.

Q.

Quadrant, a mathematical instrument; the fourth part of a circle, s. 3370. p. 544.

Quart, a small piece of board at the bottom of a jumping pole to prevent the pole sinking into the mud by the weight of the jumper's body.

Quarter-left rod, a measuring staff having four sides, s. 3195. p. 518.

Quartering, the division of planks of wood length, when made into small four-sided pieces.

Quarters of the horse's hoof, explained, s. 6420. p. 976.

Quick, a live fence or hedge formed of some growing plant, usually having quick turns.

Quick turn, sharp turns, p. 527.

Quicken tree. See Room tree.

Quickeet hedge, a hedge formed of sets or plants that are quick, that is, alive.

Quince, trees planted in rows, at the same distance between the rows that the trees are in the rows, and the trees of one row opposite the vacancies in the other, s. 3268. p. 658.

Quilt-rent, a small rent or acknowledgement payable by the tenants of most manors, s. 1117. p. 179.

Quitter, explained, s. 6898. p. 1063.

R.

Rabbit, a moulting, s. 4314. p. 713.

Rabidus, explained, s. 7410. p. 1052.

Rafter, a piece of four-sided timber used in roofs.

Raffling, ploughing half of the land, and turning the grass side of the ploughed furrow of the land that is left unploughed, s. 1166.; as applied to timber, sawing up plants of trees into pieces of greater depth than width for rafters to roof buildings.

Rake, hot, to steam or heck rut, s. 6723. p. 1608.

Ramon-headed trees, trees whose heads abound in branches.

Ramon-rooted trees, trees whose roots are much branched, p. 634.

Ray, the property of being earily ripe, s. 5062. p. 823.

Red's tail, a disease in horses, which causes the hair on the back to fall off, and not be again produced, s. 6710. p. 1067.

Reg, a disease in sheep, explained, s. 7625. p. 1066.

Rectangular fields, fields whose angles are right angles and sides parallel.

Rectangular parallelogram, a figure of four sides, whose opposite sides are equal, and all its right angles, p. 5106.

Red rod, explained, s. 5106. p. 857.

Redwater, explained, s. 5166. p. 1064.

Rëte muculæm, s. 598. A mucous membrane deposit cut a line on the surface of the epidermis and the cutis; it covers the sensitive cutaneous papilla, connects the epidermis with the cutis, and gives the power to the body. — Cracoph.

Ritina, the true organ of vision, formed by a net-like expansion of the pulp of the optic nerve, p. 977.

Rhomboid, a figure whose opposite sides are parallel and equal, but all its sides are not equal, neither are its angles right angles, p. 414.

Riddle, explained, s. 3555. p. 827.

Ricking, explained, s. 3174. p. 516.

Riddle, a large coarse sieve, s. 3535. p. 859.

Ridge, laying the soil up in ridges, p. 508.

Rigged, drawn, riving, dividing, or dividing, s. 4895. p. 601.

Right angles, where a room is exactly square, each of its angles is of it is called a right angle; in scientific language it is thus defined, as the fourth of a circle; or thus, when one straight line, standing on another straight line, makes the adjacent angles or corners equal to one another, each of the angles or corners it called a right angle.

Rigging in horses, a disease in the feet of the horse, p. 980.

Rippling of flax or hemp, the operation of separating the bolls or seed pods, by striking them against a board, or piece of iron, p. 915.

Ristle-plough, explained, s. 1197.

River-meadows, explained, s. 5769. p. 901.

Roe tree, the mountain ash.

Rough plants, spurious varieties, s. 5220. p. 873.

Rooklet, explained, s. 3195. p. 519.

Rook crops, excellent plants cultivated for their tubers, bulbs, or other enlarged parts produced under or immediately on the ground, and chiefly connected with the root, as the potato, turnip, carrot, &c.

Roots, the fibres and other ramifications of a plant under ground, and by which it imbibles nourishment. Tubers, bulbs, and other fleshly proteuberances underground, are employed by nature for the purposes of propagation or continuation, and therefore ought never to be consumed with common roots, never to nourish these tubers, bulbs, &c. in common with other parts of the plant.

Rof, explained, s. 7243. p. 1064.

Rough, the aftermath, the lattemouth, or second crop of hay cut off the same ground in one year, s. 7425. p. 515.

Rough, cattle, coarse hair or wool, p. 784.

Rough, explained, s. 7503. p. 1063.

Rovels, explained, s. 6538.

Rubbers, a disease in sheep, explained, s. 7365. p. 1073.

Rubble stones, loose stones, brickbats, and the like, which are put together to conduct water; so called because they are rubbed together.

Rumbling drains, drains formed of a stratum of rubble stones, p. 581.

Runner, explained, s. 4140. p. 675.

Russian variety of pigeon, s. 1065.

Rural economy, rural affairs, govenimens, agronemns, terms considered as synonymous with husbandry.

Rust, a disease to which the cereals and other grasses are subject, and which occasions their surfaces to be of a rusty colour, s. 7421. p. 839.

Rut, a track on the soil with a spade, p. 482; also the copulation of deer in the rutting season; also the track of a cart-wheel.

Rutting. See Rut.
S. 

Sacrebro-saltate, partaking the properties both of drink and salt, p. 1029.

Saddle-grafting, explained by figures, p. 1143.

Sallin, explained, s. 5306. p. 935.

Name, the space of animals.

Salt, a mixture given to pigeons to promote their digestion, p. 1066.

Sittings or ins, salt-water marshes, p. 747.

Sands, explained, s. 6252. p. 588.

Sauer kraft, explained, s. 5307. p. 808.

Seab, explained, s. 7506. p. 1665.

Scot: triangle, a triangle with three unequal sides, s. 4433.

Scantling, Scarcement, Scarification, Scarification, cutting through the bark and soft wood of a thick branch with an edge tool, previously to sawing through the hard wood, s. 3164.

p. 515.

Scarification, Scarcement, Scarification, cutting through the bark and soft wood of a thick branch with an edge tool, previously to sawing through the hard wood, s. 3164.

Scalene, Seed-lobes, Sea-ooze, Scllenders, Sensible, Shab, Sets, Shaking, Sheath, Shearing, Shifting or peat turning, explained, s. 3791. p. 520.

Skeen, plantations, plantations made for the purpose of skreening or sheltering, p. 753.

Shal, the outward board of the trunk from the trunk of a tree.

Sleepers, explained, s. 3785. p. 613. In Suffolk the root stocks, when left in the soil, of such trees as are sown or levelled in such places, to form an impenetrable hedge. Or rip-coat cheese, explained, s. 5753. p. 1047.

Slat planting, explained, s. 3653. p. 642.

Shab, explained, s. 3515. p. 3214.

Shackle, a single ridge, and without a curb, s. 6734. p. 1099.

Shag pruning, pruning or cutting off branches so as to leave snags, s. 1047. p. 655.

Shaws, stumpy bases of branches left in pruning, s. 2993. p. 5150.

Sol, a convulsive spasm of the air passages to relieve congestion, s. 6723. p. 1098.

Soil, earth, either of one or of several sorts, mixed with decomposed vegetable matters.

Soiling, feeding horses or cattle in houses or sheds with clover or other herbage in a green state, p. 574.

Sow, a horse, s. 4106. p. 700.

Soor, explained, s. 5146. p. 628.

Spray, to incapacitate a female animal for producing young, s. 7506. p. 1099.

See Grass: Sow-land, a stock or rip of straw formed in a barn, s. 5945. p. 818.

Sprout, a weed, s. 3642. p. 1062.

Springs, processes, projections resembling spines or prickles, s. 6504. p. 1061.

Sprored, grown, shot out into spires, s. 5109. p. 825.

Spitful of earth, a spadeful of earth, p. 567.

Splant, in horses, a pre-natal presence of earth, or a hard tumour, s. 6593. p. 504.

Spots, a variety of pigeon, s. 1065.

Spray drain, a drain formed by burying the spray of wood in the earth, which keeps open a channel, s. 4914. p. 708.

Spray of a tree, the twigs of the branches of a tree, s. 649.

Sprout, a weed, s. 5945. p. 818.

Sprout, a weed, s. 5945. p. 818.

Spitting, the process of mowing the plants which abound in rivers; the instrument with which this is effected is formed of a line of seythe-blades, rivetted together by their extremities, and with the line of seythe-blades as worked or turned along over the surface of the mud by levers attached to the line, operated upon by men in boats, s. 3171. p. 515.

Shift of crops, an alternation or variation in the succession of crops, p. 814.

Shift, a beach of gravel liable to be shifted or moved by the action of the sea, or the current of rivers, s. 3522. p. 714.

Shingles, pieces of thin board used as tiles, a common practice in timber countries on the Continent and in America, s. 4001. p. 495.
GLOSSARY INDEX

Sunning, explained, s. 4152. p. 674.
Sturdy, explained, s. 7297. p. 695.
Subcarbonate of soda, a salt in which soda predominates, p. 857.
Sanguine, under the tongue, s. 6788. p. 972.
Swath, a substitute, s. 848.
Stem, the bands or ridges produced by mowing with the scythe, p. 903.
Stemath, the line between two swaths where the stubble is cut least closely, presenting a little ridge of stubble, p. 514.
Swags, long braimle rods used in thatching with reeds, s. 518.
Swathing, a slight fermentations, p. 904.
Swing plough, any plough without wheels, s. 390.
Switching hedges, an instrument used in pruning hedges, p. 485.
Switching hedges, cutting off the one year's growth which protrudes from the sides of hedges, s. 4406. p. 652.
Synchronous, at one time, at the same time, contemporary, s. 1002.
Synonym, s. 6327. p. 968.
Tag-belt, a disease in sheep, explained, s. 7250. p. 1005.
Tail drain, explained, s. 1414. p. 78.
Tapestry, explained, s. 6783. p. 970.
Tarsus, explained, s. 6532. p. 985.
Teaing, explained, s. 8584. p. 986.
Tecerma, explained, s. 7141. p. 1052.
Tedding hay, scattering, spreading, turning, and, in some respects, explained, s. 943.
Teaon, a projection in a rail, &c, made to fit a mortice.
Teazon joint, a joint formed by a tenon and mortice, explained, s. 6388.
Tenure, a holding or occupying, p. 175.
Territorial economy, whatever relates to the valuation, purchase, sale, exchange, arrangement, improvement by roads, canals, drainage, &c, of territorial surface, including interposing waters, and rivers, lakes, and also mines and minerals. Territorial improvements are mostly effected by the proprietors of lands or their agents and stewards, and not to any great extent by renters of land, or farmers.
Tetanus, a spasmodic affection, accompanied by rigidity, one species of which is known by the popular name of a locked jaw, s. 6570. p. 970; s. 642 p. 978; s. 9655. p. 1052.
Tethering, restraining grazing animals by a rope or chain, fastened to the animal at one end, and to the earth; the other, s. 3500. p. 876.
The time of drought, the direction in which an animal is pulling or drawing, s. 2592. p. 289.
Thatching, an instrument used in surveying, and chiefly in taking angles, p. 544.
Thill, the beam or draught tree of a cart or waggon.
Thiller or Tull horse, the horse that is put under the thills, or shafts of draughts or ploughs, s. 1138.
Thoracic duct, the trunk of the absorbent vessels, so called from its being placed in the thorax or chest, explained, s. 6293. p. 981.
Threave, twenty-four sheaves of straw or corn, s. 1058. p. 517.
Thrush pine, explained, s. 5655. p. 988.
Tibia, the leg bone, s. 963. p. 1053.
Ticks, a variety of bee, called the tick bee, s. 7952. p. 986.
Tie, a bar so placed as to resist a drawing or twisting power, p. 493.
Tin oxide, a obsolete land, p. 416.
Tiller, to send forth numerous stems from the root; applied only to culmiferous plants, s. 4984. p. 804.
Tillering. See Tiller, s. 5231. p. 825.
Tilting, the degree or depth of soil turned by the plough or scythe, that available soil on the earth's surface, into which the roots of crops strike, p. 903.
Tinting, is applied to hay-making, explained, s. 6518. p. 875.
Tithes, the tenth of the produce of the soil, paid to the clergy or landlord.
Tithing-man, a person employed by the clergyman in a village to set out and collect his tithes.
Torrified earth, earth subjected to the action of fire, p. 302.
Träcker, the windpipe, p. 972.
Tackling hair, breaking the woolly part in the stems of flax, s. 9041. p. 915.
Tramp, an instrument used in making hedges, p. 418.
Transcurrent, transparent, diaphanous, allowing light to shine through, p. 811.
Trench, explained, s. 7253. p. 1065.
Trice, explained, s. 4412. p. 730. To trench, to turn over and mix soil to the depth of two, three, or more spades, or spits.
Triad, to allow to trickle or run down in small streams, p. 614.
Trolley, an instrument resembling a pipe, used for making incisions, when water or air is received out of the incision through the trochar, p. 1074.
Truncate, long, large, sticks, or poles, of willow, poplar, &c, planted to form trees or hedges, p. 719.
Trumpeters, a variety of pigeon, p. 1065.
Tubers, knobs, fleshly bodies at the roots of plants, as in potato, yam, pignut, &c, s. 511.
Turners, a variety of pigeon, p. 1065.
Tufted, explained, s. 7257. p. 1062.
Tussocks of grass, clumps, tufts, or minute hillocks of growing grass, p. 518.
Twill and kins, explained, s. 5171. p. 832.

U.

Urinaria, a receptacle for urine, s. 6988. p. 1038.

V.

Vlum pollu, explained, s. 6382. p. 972.
Vina cava, explained, s. 6338. p. 967.
Vina cava ascendens, explained, s. 6348. p. 987.
Vincia ascendens, explained, s. 849. p. 987.
Vina pate, explained, s. 6349. p. 967.

Vioo. See Pining.

Viooi, thick, glutinous, gummy, p. 1083.

Vitiosum, living, sprouting, very lively, very free of growth, p. 903.

Voex, explained, s. 6388. p. 972.

W.

Wads, explained, s. 5008. p. 836.
Waals grilled with lime. See Harded.
Water, the water built of mud rammed in between a frame of boards, s. 457.
Water-bank, explained, s. 6549. p. 984.
Water-holding, explained, s. 5492. p. 852.
Watering, explained, s. 4452. p. 732.
Watering, the maceration, steeping, or immersion of the stems of the hemp plant, in water, s. 677. p. 107. p. 917.
Water-rolled, watered, s. 5920. p. 917.
Water tables across a road, sunk pannels, which conduct the surface water into drains, p. 582.
Water-rolling, explained, s. 5014. p. 486.
Waterhead, explained, s. 7207. p. 1006.
Wattle, to weave, to interlace, or plat branches or rods.
Wattled fence. See Stake and Rice.
Wattled hurdles, hurdles wattled with rods.
Way pane, explained, s. 4412. p. 730.
Wear, a darn made with staves and osiers twigs intertwined, as a fence against water, p. 722.
Well-bred, explained, s. 5001. p. 356.
Wherewith, explained, s. 6871. p. 1035.
Whin, fence, gorse, gorse, or goss, p. 510.
Whistle, explained, s. 5034. p. 592.
Whipping out grins, striking the ears against a stone or the edge of a board, till the corn is separated from the straw, p. 519.
Whipping in plants, to bruise, abrasive, or injure, by rubbing or striking against another, as the competing branches of neighbouring trees, s. 4414. p. 663.
Whelkbone of the horse, the articulation of the thigh bone with the pelvis, s. 939.
White, the small-leaved lime, p. 1141.
W Hilfe, trees springing up from seeds naturally distributed, by winds, birds, running waters, &c, s. 675.
Wideostraw, the withered flower-stalks of grasses standing in the fields; in English, bents, s. 5408. p. 826.
Wielars or puckeridge, explained, s. 6988. p. 1063.
Wool-hair, a land-receiv or ground officer, s. 6468.

Y.

Yellow, explained, s. 6490. p. 984.
Yeering, one of the motions taught to horses, s. 6672. p. 1062.
GENERAL INDEX.

ABBATE, Antonio, his work on agriculture, page 1221. A. D. 1808.

OF

AGRICULTURE:

BRINGING DOWN IMPROVEMENTS IN THE ART OF FIELD CULTURE FROM 1841 TO 1843 INCLUSIVE.

Author of the Encyclopædia of Gardening, and Conductor of the Gardener's Magazine.
INTRODUCTION.

The improvements in agricultural science and practice, which have been either discovered, or brought more conspicuously into notice, since the publication of the last edition of this *Encyclopædia* in 1831, may be thus briefly enumerated.

1. The functions of the leaves of plants are beginning to be more generally understood; and hence, also, the importance of allowing sufficient space for their exposure to the sun and air, by wider sowing or planting, by judicious thinning, and by pruning.

2. Growth and maturation in plants are two separate processes, and when either is the main object of culture, the other should be prevented or checked; thus when seeds or fruits are maturing, the elongation of shoots and the production of leaves should be checked, by pinching them off as fast as they appear. Hence the use of topping beans, tobacco, woad, and even potatoes; not to mention vines, gooseberries, raspberries, peaches, and other garden fruit shrubs and trees.

3. By preventing the formation of seeds or fruits, more strength is thrown into the plant generally; and if it is a plant which produces bulbs, tubers, or underground stems, as substitutes for seeds, these will be increased in size. Hence the use of picking off the blossoms of potatoes.

4. Plants imbibe nourishment from the soil, chiefly from the points of the fibres at the extremities of their roots. Hence the practice of banking up hedges, beans, potatoes, and other plants in drills, and of watering, stirring the soil, and laying manure close to the stems of trees and plants, is erroneous in principle and often injurious in effect; by cutting off the fibrils, or, in the case of potatoes, the underground shoots on which the potatoes are formed. In some cases, however, cutting off the extremities of the roots is useful by increasing the number of fibrils, and consequently of the sponges or mouths by which nourishment is imbibed.

5. The Berwickshire practice of tabling hedges so much recommended, and so generally followed by Scotch bailiffs, foresters, and hedgers, is for the most part a waste of labour; unless, indeed, the object be to stunt the growth of the hedge, and prevent its roots from robbing the soil of the adjoining fields. The practice of earthing up turnips was once in vogue, but it is now ascertained to be a certain mode of instantly checking the swelling of the turnip, by the pressure of the soil which is thrown up to it by the plough.

6. The progress of the ripening of seeds and fruits in general goes on in a geometrical ratio, and hence the great nicety required to determine the moment when seeds or fruits should be gathered, which period varies according to the purpose to which the seeds or fruits are to be applied. The last change which takes place in the ripening of wheat is an increase of bran or husk, and a relative diminution of farinaceous matter or flour; and hence the immense difference in the produce in flour, between that of the grain of a field of wheat cut down at the proper time, and a field of wheat allowed to be over ripe. Too much importance can hardly be attached to this subject.

7. Running water is found to contain oxygen, potash, carbonic acid gas, and ammonia, all which serving as manures for plants, it follows that irrigation, even in cold climates, is beneficial to grass lands, altogether independently of supplying water as an element of growth, which in cold climates is seldom wanted in that capacity.
8. More importance is now being attached to the ascertaining of the mineral constituents of plants, such as alkalies and alkaline earths, phosphorus, sulphuric acid, silica, &c., than was the case before the appearance of Liebig's *Organic Chemistry*.

9. The permanent fertility of a soil is found to depend more on the inorganic substances which it contains, (for example, on the proportion of alkalies and alkaline earths which it holds in combination with the silieie, phosphoric, sulphuric, and other acids,) than on its organic constituents, such as humus or decaying vegetable matter: for all organic matter in soil, whether that soil be naturally good or bad, is sooner or later exhausted by the growth of plants; and if the supply is not kept up, the soil reverts to its original state, except in so far as it may have been improved mechanically by draining, levelling, shelter, &c.

10. Plants absorb their carbon chiefly in the form of carbonic acid, and not, as was supposed till lately, solely in the form of a solution of humus.

11. Plants derive their carbonic acid principally from the atmosphere in the form of carbonic acid gas; and the chief use of humus or mould in the soil, is to combine with the oxygen of the atmosphere, and thus to supply an atmosphere of carbonic acid to the roots. Hence the inutility, and often dead loss, of burying putrescent manure to such a depth as to exclude it from the air, and the more immediate return made by manure spread on the surface of the ground among the leaves of plants, as in manuring meadow lands, and top-dressing spring crops of corn, or artificial grasses.

12. The process by which carbonic acid is generated by oxygen from humus, depends on the soil being permeable to air and moisture; and hence one of the principal uses of draining and pulverisation.

13. Alkalies are the most important inorganic constituents of soils, and when a soil has been exhausted of them by cropping, no manure that does not contain alkalies will restore their fertility for agricultural plants.

14. The poorest soils are almost invariably those which contain least alkalies and alkaline earths.

15. Animal manures contain a much greater proportion of the inorganic constituents of plants, than vegetable manures; and the most powerful of animal manures are those of carnivorous or omnivorous animals; for example, of the human species.

16. The most valuable part of manure is ammonia, from which plants derive their nitrogen, which, though formed only in small quantities in plants, is yet essential to the ripening of their seeds; and hence the great value of urine.

17. Next to ammonia, the most valuable manure is potash, which in the form of silicate is the principal constituent in the straw of wheat.

18. In consequence of knowing the ingredients which constitute a good soil, all lands the slope of the surface of which is not so great as mechanically to prevent their being readily cultivated, may, by the addition of the ingredients wanting, and by proper culture, be raised to the highest point of production that the climate in which they are situated will admit of.

19. To know what can be effected in the worst soils in any given climate, it is necessary to have a conception of what can be done on the best soils in such a climate. Twelve bolls (48 Winchester bushels) per statute acre is not an uncommon crop in the best soils and situations in the Lothians; and less than 10 bolls (40 bushels) per acre is not considered a full crop. The average produce of wheat in England and Wales, however, is only 2 1/2 bolls, or 26 bushels, per acre! It is believed by most scientific agriculturists that every soil and situation in Britain, capable of growing wheat at all, is capable of growing from 8 to 10 bolls or sacks (92 to 40 bushels) per acre, if properly cultivated.

20. Next to animal manures, the most important ingredient that can be added to soils is the ash of plants, because it contains all their saline constituents.

21. Saline manures not only supply food, but, acting as stimulants, enable plants to derive more food from the soil and the atmosphere than they otherwise would do. (Chatterly in *Phil. Mag.* 1843.)

22. Plants containing the smallest quantity of alkaline salts flourish in the greatest variety of soils, and the contrary.

23. The office of food is two-fold: to supply the body with nutriment or flesh, and to supply heat and fat.

24. Only those substances can supply flesh which contain nitrogen; and starch, sugar, gum, and other substances which contain carbon, oxygen, and hydrogen, without nitrogen, only supply heat and fat.

Hence neither pigs nor human beings who live chiefly on potatoes can derive flesh from that kind of food, without the addition of milk, or some other animal matter, or of corn, pulse, or meal of some kind which contains gluten. Hence the Irishman's cow is as essential to his existence as his potato ground.

25. Hence a knowledge of the chemical constituents of plants is useful, not only in
ascertaining the manures proper for being applied to them, but also for knowing their application to the feeding or fattening of animals.

Hence, also, no system of agriculture or horticulture can be considered complete which does not give an analysis of the chemical constituents, not only of the plants of cultivation, but of the weeds of the locality. In a word, the chemical constituents of every individual plant are just as essential to be known as its physiology and systematic character; and indeed a great deal more so. A century hence, or in less time, it will be wondered by scientific cultivators how the present generation could go on without this knowledge.

26. Warmth, to a certain extent, is equivalent to food; and hence the great benefit derived from sheltering cattle during winter.

27. Exercise is for the most part a waste of food, and hence the advantage of stall-feeding cattle, and confining pigs and poultry in a limited space; it does not follow from this, however, that confinement should be carried so far as to render the flesh of the animals unwholesome.

28. In the case of milk cows, rich pastures, or other food abounding in carbon, produce the greatest proportion of butter; while poor pastures, by requiring the cow to take more exercise, increase the proportion of the caseous part of the milk.

29. The various new manures which have been introduced are either of organic or inorganic origin. The action of inorganic manures, such as nitrate of soda, common salt, &c., is not uniform, and in some cases is not perceptible; but the action of organic manures, such as guano, pourette, rape or oil-cake, and vegetable alkalies, such as potash, is certain, and always beneficial if not applied in too great doses.

30. All clays contain potash, and also all soils produced from rocks containing felspar, zeolite, albite, and mica; and hence one cause of the value of basaltic and granitic soils.

31. The application of burnt lime to clay, independently of other effects which it may produce, liberates potash.

32. The action of burnt clay (which generally contains oxide of iron) to soils, independently of its mechanical properties, is as an absorbent of ammonia from the atmosphere.

33. The addition of clay to sandy soils containing calcareous matter, increases the quantity of potash which they contain; but if the sand contains no calcareous matter, it merely improves their mechanical texture.

34. The ammonia of liquid or other manures may be fixed by gypsum or sulphuric acid; or, in default of these it, may be prevented from evaporating by mixing with soil or diluting with water. In general the most convenient and economic mode for the British agriculturist is to mix it with farm-yard manure, or, what is better in our opinion, plenty of surface soil.

35. The chief practical advantages which have as yet resulted from the recent discoveries in chemistry, as applied to agriculture, are, the employment of saline manures, and the recognition of their importance, the mixing of azotised (nitrogenised) with unazotised (unnitrogenised) food in feeding and fattening cattle, and the procuring greater warmth for the domestic animals of the farm.

36. The most useful practices which have obtained extended diffusion within the last ten years are, the frequent drain system, long practised in Essex and Suffolk, but recently brought conspicuously into notice by Mr. Smith of Deanston, the use of draining-tiles instead of stones, the use of the subsoil plough, and of the cultivator as a substitute for the plough in various cases, the greater cagerness to procure improved implements, machines, and buildings generally, the mixture of soils, the greater value set on urine and liquid manure generally, the use of single-horse carts, the selection of improved varieties both of animals and plants, and the employment of land agents conversant with agriculture, instead of lawyers or others who have little or no agricultural knowledge.

The details which have led to the above summary will be found in Liebig's Organic Chemistry, and Animal Chemistry; Johnston's Agricultural Chemistry; Trimmer's Practical Chemistry for Farmers and Landowners; Solly's Rural Chemistry; Dr. Playfair's Lectures on rearing and feeding Cattle, published in the Journal of the Royal Agricultural Society, vol. iv.; Donaldson's Manures, Agricultural Grasses, and General Management of Landed Property, &c. The greater part of this Supplement consists of extracts from these works; and from the Quarterly Journal of Agriculture, the British Farmer's Magazine, the Gardener's Chronicle, and the Gardener's Magazine.

Bayswater, August, 1843.

THE

ENCYCLOPAEDIA OF AGRICULTURE.

PART I.

AGRICULTURE CONSIDERED AS TO ITS ORIGIN, PROGRESS, AND PRESENT STATE, ETC. (p. 4.)

ITALY.

7931. — 274. An oil, not fit for the table, but useful for burning and other purposes, has been obtained by expression from the fruit (keys) of an Acer Nigricanum fraxinifolium. The experiment is of some importance with reference to Britain, as it shows that in all probability an oil may be obtained from the keys of the common sycamore, A. cer. Pseudo-Platanus; and also from the common maple, A. cer. campestris. See the details respecting the oil obtained from the negundo in Gard. Mag. 1842, p. 46.

1842. — 298, The olive, we are informed by Manetti, is propagated by cuttings, by seedlings, and by grafting. By cuttings is the most valuable mode when the soil is good, as the plants come soonest into a bearing state. Where the soil is poor, and especially if it be rocky, seedlings are to be preferred, because they send down their roots into the crevices of rocks, and thus derive nourishment and support, where plants raised from cuttings would not live. In Tuscany, the olive is very generally raised from seed, and in many situations it is grafted. In Lombardy, on the Larian Hills, trees raised from cuttings are always used, and this is the reason Manetti alleges why these trees have their trunks perpendicular to the sides of the hill, instead of perpendicular to the horizon. Some interesting discussion on this very singular appearance will be found in Gard. Mag., vol. viii. p. 68 to 76.

7933. — 299. The cause of malaria, in this and other pestilential districts of Italy, has generally been supposed to be the decomposition of vegetable matter on a moist surface. This, however, is to confound the malaria with the marsh fever. The former is now thought to proceed from a very different cause, and to be analogous to what in England is called the hay fever. It is found that, while the corn or hay crop is in a growing state in the pestilential districts, they are as healthy as any part of Italy; but that the moment the crop is cut down, or withers on the ground, the malaria commences, and continues through the autumn and winter, till vegetation becomes vigorous in the following spring. The neighbourhood of Rome, where malaria is so prevalent, "is very hilly, dry, and entirely without vegetation. For days together, one sees nothing but bare earth, and the dried-up clay holds not trees, bushes, or wood of any description. In early times, Rome was surrounded by extensive sacred woods, which were not suffered to be destroyed. At that period malaria was unknown, though intermitting fevers were well known in the Pontine marshes. (Jameson's Jour. vol. xvii. p. 167.) In several districts in England, the country people are liable to attacks of fever immediately after the removal of the hay crop, some individuals much more so than others. This may be considered as a species of malaria of a comparatively mild description. See on the agriculture of Italy generally, an extract from the astronomical part of the Atti della Terra Rionale degli Scienziati Italiani, Florence, 1842, 4to., in the Gardener's Chronicle for 1842. "No kind of potatoes has hitherto succeeded in Tuscany, owing to the great drought and heat, which destroy the herbage in the month of August. In mountainous situations they succeed better; but they are for the most part grown only in gardens, where they can be constantly watered. The sweet potato, Convolvulus Balbina, succeeds much better, as it naturally can stand a greater degree of heat, while its copious herbage covers the ground, retains moisture, and affords a superior fodder for cattle." (G. C., 1842, p. 679.)

FRANCE.

7934. — 380. The backwardness of agriculture in France "is mainly attributable to the very partial spread of education in the rural districts, there being out of 40,000 communes, according to M. Dupin, 18,000 institut of teachers; and out of 20,000,000 inhabitants, who have reached a teachable age, 10,000,000 only are able to read. Now as the small independent proprietors of land amount to 1,000,000, and their families to 12,000,000 or 14,000,000 more, it is obvious that this state of ignorance must, under such circumstances, be attended with far more prejudicial effects upon production than if it existed in England, where the labourers are under the orders of about 32,000 large proprietors, and the success of cultivation consequently does not so mainly depend upon the general diffusion of knowledge. It is gratifying to find, however, that the large proprietors in France are universally desirous for the instruction of the rest, and that schools, rural schools, and model farms have been established under very favourable auspices." (Far. Quart. Rev. 1829.) A national system of public instruction was established in 1832, and the various details will be found in the Bulletin de la Société pour l'Instruction Élémentaire, for that year. An account of the present state of French agriculture, and of the state establishments in that country, such as sheep farms, model farms, veterinary schools, haras or studs, will be found in the Journal of the Agricultural Society of England, vol. i. for 1839, p. 592; and the statistics of French agriculture is given in the same work, vol. i. p. 411.

7935. — 381. Present state of French agriculture. In L'Agronomie, a monthly agricultural journal published in France, at the low price of five francs a year, it is stated in the first number, published in January, 1835, that in France "the colonies afford no longer the means of making a fortune; the convents do not provide a remedy for the want of foresight of parents; the system of peace, which is every day procuring more advocates among the most highly civilised of the people, no longer offers a brilliant..."
prospect in the profession of arms; commerce and manufacture suit only particular characters; the sciences and the professions only minds privileged by nature; while agriculture alone offers opportunities to all. After Culture and bread have been produced, or, in other words, when the country is in a sufficient state, that the business of a farmer must no longer be that of men who are not fit for any thing else; but it must be adopted by men of education, and pursued assiduously and systematically. It appears, from these reasons, that the cultivation of France publickly established, that extraordinary influence, is the introduction of the agricultural improvement of that country. Among other points to which the attention of the cultivator is directed, is the necessity of feeding his men well, no less than his horses. As a proof of the advantages of doing so, it is stated that when Messrs. Manby and Wilson, from Longbrough, established their new work at Foxville, in the Valley of the Meurthe, about six leagues from Nancy, by M. de Dombeale, a skilful practical agriculturalist, it comprises clay, sand, and gravelly soil; and the proper modes of culture are applied to each. By the improvements in ploughs and instruments of husbandry, five horses and nine oxen now accomplish at Foxville more work than thirty-five beasts of burden used to do on the same ground. With the aid of the Scotch three-hing-machine, M. de Dombeale beats out, with three horses, three hecatolitres and a half (upwards of an imperial quart) of wheat, and other grain in proportion. Potatoes are cultivated with attention, and a distillery has been established for extracting the spirit. M. de Dombeale has proved what will, we think, excite some surprise, that land of a middling quality, planted with potatoes for fattening beasts, will be more productive than the richest meadow. No stranger encouragement can be made on this subject. The potato has more power than that fact that he taught to the French, who, the average annual return of Foxville being 59 francs per hectare, while that of the rest of the department of the Meurthe is but 2-3 francs per hectare. At Money, in the department of the Moselle, the model-farm of M. Bouchelette is famous for its breed of horses. (For. Quart. Rev.)

The agricultural societies of Alsace (lib. 1836) has had in Itzehoe a plantation of fruit and forest trees in Alsace; a want observable not merely in that department, but throughout the whole country, except, perhaps, Normandy and parts of Brittany. In Franche-Comte, and the department of Dombasle, the breed of cattle has been diffused among a breed of the most modern character; the horses, as has been observed, that of the most modern character; the horses, as has been observed, have been greatly increased under the influence of the society. The agricultural society of the Seine and Oise, which comprises many extensive landed proprietors, bestows, annually, medals and prizes on the small cultivators who turn their hereditary estates to the most profit, and upon the hired labourers and servants employed in large farms, who perform their work with the greatest intelligence and fidelity. A model-farm has been lately established at Roiville, in the department of l'Yonne, on a farm of 7,000 acres, and of various nature, called the farm of M. Richardot, a small proprietor, has given an impulse to planting, and to a systematic irrigation of the land. (Ibid.)

The vine is a department of their husbandry of which the French are particularly proud, and with good reason. The vineyards of the Lorraine and Rhine, which have been, for more than 1,300 years cultivated under the same latitude as the south of France, has never been brought to an equal degree of perfection. The plantations of vines have been and are subject to severe discouragements, but have, nevertheless, increased very considerably over their extent in 17-9. In that year their surface was estimated at 1,200,000 hectares, and increased to 1,600,000 in 1814. The yield of wine from the vines occupied about 2,000,000 cultivators, and their annual produce was computed at 40,000,000 hectolitres; the value of which, at fifteen francs per hectolitre, is 600,000,000 francs, or about 24,000,000 sterling. This supply is sent to Paris annually is valued at 17,000,000. At Origny, in the neighbourhood of Vervins, the children of the husbandmen are employed in making baskets, &c. of willow, to the value of 40,000 per annum. In Champagne, the example of M. Richardot, a small proprietor, has given an impulse to planting, and to a systematic irrigation of the land. (Ibid.)

The vine climate. Strabo (ib. iv.) says, that the line of the Cevennes, in Gallia Narboensis, was the northern limit, beyond which the cold prevented the growth of the vine. The limit is still in the same position. (Jannaeus's J. J. April, 1833, p. 233.)

The French pigs, although they have excited many facetious observations from travellers, are very serviceable to the French farmers, as they are of a low price, they are very labile, and require a very small amount of both capital and expense; and the method of doing this is now beginning to be better understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, and the extent to which they are fed, is now being considered as better understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, and yet, not the least attention is paid to the stock they are derived from, gives rise to the idea that they are not raised, but under a very cheap and easy means. (For. Quart. Rev.)

The French pigs, although they have excited many facetious observations from travellers, are very serviceable to the French farmers, as they are of a low price, they are very labile, and require a very small amount of both capital and expense; and the method of doing this is now beginning to be better understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, and the extent to which they are fed, is now being considered as better understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, and yet, not the least attention is paid to the stock they are derived from, gives rise to the idea that they are not raised, but under a very cheap and easy means. (For. Quart. Rev.)
Holland.

7933. 

7934. There are few large estates in Holland, and "but few large farms. The land being remarkably level, it is generally divided and cultivated by ditches, or narrow canals, that receive the surface water, and serve the purposes of a fence." (Ibid.)

7935. The farm-houses in Holland "are of dimensions suited to the extent of the land in the farm, and they are more or less elegant or comfortable, as those who have a female assistant, and the inhabitants seem to be pleased in Holland, probably on account of the soil being naturally rich." (Ibid.)

7936. The cow byre is "paved with hard bricks, or clinkers, as they are termed, set on edge; and the stakes to which the cows are bound are made to be removed in summer, when the cattle are turned out to pasture. Before the cow is driven to the byre, the cow-house is thoroughly dried, and the clean water is placed where the cows can drink at pleasure. The water is let off once a day by means of a plug, and a new supply from the well pumped into the trough. A passage behind the house is necessary to remove the dung." (Ibid.)

7937. Dutch cows. "The Vriesland and Groningen cows are the largest and most esteemed races in Holland. They are short-necked, broad and deep-chested, deep bodied, and broad-backed, with well-made limbs, fine small horns, and stand well upon their feet. The greatest number of these cows are with white, or dun, or brown; with white feet. (Highland Soc. Trans., vol. x. p. 169.)

7938. The general practice in Holland is," that the cow should calve in her second year. The bull is employed when it is two years old, and is fattened and sold to the butcher when four or five years old, and the cow is kept for milking the tenth year." (Ibid.)

7939. The most improved method of treating the calf in Holland. "It is immediately after its birth taken from the cow, put in a separate place, and laid on dry straw. A little salt is given, and the tongue and mouth are rubbed with water. It is also rubbed clean with straw. After the lapse of six or eight hours, the first sucking of the mother cow, diluted with one third water, is given to the calf to drink, and this treatment is continued for some days, the liquid being given thrice a day. Thereafter, during two or three weeks, they give the calf the milk as it comes from the cow, diluted with one fourth water, in which it is freely hand-fed; then buttered milk is given; but, at the age of ten weeks it is brought out into the meadow, where it is also supplied with skimmed milk, buttermilk, or whey. In this way each farmer raises the proper number of heifer calves to succour his cows, which have three red and white heifers to each cow, and after two years, even after two years, they are allowed to milk twice a day." (Ibid.)

8000. Treatment of milk cows in Holland. "The cows are turned out to grass generally by the end of March, near Sasvent, and to dry cows in the beginning of April. They are, when first sent out, furnished with a very thick cloth of oil, covering the back and sides of the shoulders to the tail, to prevent diseases from cold. They remain out, night and day, about thirty weeks. In the winter months the general food is hay, and most farmers give their cows nothing else; distilled grains are sometimes given, when they can be obtained. At the great establishment of Baron Van Pallink, near Leyden, rolled beans, with rape cake, spread over the hay, were given at night, and ground linseed cake in the morning, which, it was stated, enabled the cow to give more and better milk than hay alone. Raw potatoes can be much more taken if also dug up than those of the farm-houses in Scotland. They have a stone of an elegant figure, which is kept wonderfully clean. The wall near to the fire-place is covered with plates of flowered earthenware; and the mantel-piece is richly, though rather heavily, fitted up. There are some concealed beds and cellars in this part of the house for washing the butter, are it may be said, an inclosure, near the central building. The floor of the kitchen generally consists of marble; the building of the house is of brick. The gincourse is laid with sand, and is covered with boards when the horse is to be kept in it. It rises in a very short form. The walls are generally built of brick, but sometimes of mud or boards; but the roof is supported upon trusses of wood, round which the walls form only a covering. There is no urine tank as in Belgium. Indeed, there is attention seems to be paid to manure in Holland, probably on account of the soil being naturally rich." (Ibid.)

8001. The byres or cow-houses in Holland are generally lofty, airy, provided with large square bricks (Aiton, vol. xi. p. 136.) 7966. They are perfectly clean. The ceilings are generally about ten feet high. There are no racks or mangers. The cows stand in two rows, generally facing the centre, and sometimes the sides of the byre, along which is a brick pavement slightly elevated in the middle. On the edges next the wall of the house, perfectly confined, into which they are allowed to drink, with the mouth open, without any help; and the hay laid down. Each cow has about five feet of space, and is tied to a railing of three small posts in front, which separate them from one another. There is a little straw used for bedding; on the house where the cows stand, there is a hollow part at the fire end, or in the roof, where the air now and then comes in. There is also a little straw at the head. From the narrowness of the space divided into stalls, the back always projects so far as to cause the dung droppings to fall into a gutter about eighteen inches deep, and eighteen inches wide, which is regularly and carefully cleaned away and dried and cleaned away in the gutter. The cows are always kept quite clean; and, to prevent the tall occa-lioning filth, the lower end is always tied up by a string attached to the ceiling." (Ibid.)

8002. Process of milking in Holland. "The cows are always milked by the men, and the butter and cheese made by the women. One man is considered necessary for every ten cows. At Ter Leide, the well-managed dairy establishment of Baron Van Pallink, there are ninety milk cows, nine men, and a Boerem (or female farmer), the maker of the butter and cheese. At Klukken, the farmer and his wife and three young sons do all the milking, and his wife and one female servant make all the butter and cheese. At Schoote, near Haaren, there are
twenty cows; the father and son milk, and the wife and a female servant make the butter and cheese.

1885. Butter. There are three distinct kinds of butter manufactured in Holland; the butter made from the cream, when the cow is at grass in the summer, called grass butter; the butter from the whey of the new milk cheese, called whey butter; and the butter made in winter, when the cows are in the cow-house, called hay butter.

1886. Grass butter. "The cows being carefully milked to the last drop, the capper pitchers lined with brass, or pitchers entirely of brass, which contain the milk, are put into an oblong water-tight pit, which sinks at least six feet into the ground, about six inches in depth, into which cold water had been previously pumped; there being generally a pump at one end of the pit. In this pit or cooler, the pitchers stand two hours, this milk being frequently stirred. The cooling process is of great advantage in the cream to separate rapidly and abundantly from the milk. Afterwards the milk, being run through horse-tail sieves or cleaners which are of earthenware, copper, or wood, as will be afterwards described; it remains in a cool dairy or cellar for twenty-four hours. It is then skimmed, and the cream is collected in a tub or barrel. When souring, if there is a sufficient quantity of souring from the two previous days, the churn being half filled with the sour cream. A little boiled warm water is added in winter, to give the whole the proper degree of heat; and in very warm weather the cream is first cooled in the rodik or cooler. In many small farm-houses, or when the cow is not in the churn, the milk is put into a shallow tub called a boot, and carefully washed with pure cold water. It is then worked with a slightly sprinkling of small salt, whether for immediate use, or for the barrel; there being none made entirely without salt, it is either put directly into the churn or is processed as small butter made in winter, when the cows stand in the cow-house. But, although inferior in flavour and colour, it has none of the disagreeable taste which the turnip imparts to the winter butter of Britain."

1887. Whey butter is made from the whey of the new milk cheeses. The whey, being collected from the curd, is spread through the coagulated to stand three or four hours; the cream is either skimmed off and churned, or the whey itself is put into the churn, and is churned in about an hour. In winter the butter obtained by this process is about one lb. per cow per week, and a good cow will yield a half per cow per week.

1888. Cheese. There are four kinds of staple cheese made in Holland: the round or bullet cheeses, called Edam (from their having been first principally made in that neighbourhood); Stolkshe (so called from Stolk, a township in British Guiana), which are called in Dutch Stolkshe; Gouda cheese, which is better than the Edam, both kinds being made of unskinned milk; Leidsche or Leyden (being so called from this kind of cheese being principally made near Leyden), which is made of milk once skimmed; and Grauwsche, which is made in Friesland, of milk twice skimmed. Both the latter kinds are called Kanten cheeses and are larger and flatter than the former, and have a peculiar firmer and drier texture.

1889. Edam cheese. "The process of manufacture of the Edam cheese is as follows: — The rennet is put into the milk as soon as it is taken from the cow; when coagulated, the hand, or a wooden bowl, is passed gently, two or three times through the curd, which is allowed to stand a few minutes; the grass and hay butter is slightly perceptible; but the grass butter, after the cows have been three weeks at grass, is delicious. This new butter is highly esteemed in Holland; it is made in fanciful shapes of lambs, pyramids, &c., or stuck with the flowers of the polyantus, &c., and sells very high. If intended for barrelling, the butter is worked up twice or thrice a day with soft fine salt, for three days, in a flat tub, there being about two pounds of salt allowed for fourteen pounds of butter; the butter is then packed thick in thin layers into the casks, which casks are previously carefully seasoned and cleaned. These casks are made of oak, well soaked in water, and left three or four days, filled with sour whey, and are then carefully washed out and dried. Each cow, after being some time at grass, yields about one Dutch lb. (17¼ oz.) of butter per day." (Ibid.)

1890. Gouda cheese. "The cheese is made as great a part of the cheese process as butter made in winter, when the cows stand in the cow-house. But, although inferior in flavour and colour, it has none of the disagreeable taste which the turnip imparts to the winter butter of Britain." (Ibid.)

1891. Kanten cheese. "The name given to this cheese is from a place in Zeeland, called Kanten, through a mixture of the words kaas, cheese, and rent, rent."
cloth round it. It stands in this form twenty-four hours, the cloth being taken off and wrung dry three or four times a day during these twenty-four hours: this form is placed upon a hand-barrow, or open standard, over a tub, which receives the whey. After this form, or the lid is removed, it is frequency pressed by the weight of the body. The cheese is then taken out and put into a cheese-well, or form, equally strong, having a cover called a rogjer, and put under a heavy press, the weight being allowed to be taken four hours more. This pressure is then taken off; and when taken out of the press, the cheese is washed, and in some places it is smoothened by rubbing it frequently with some commin seed, and then follow regular layers, with cloves intermingled, until the upper layer is placed which has no spices in it.” (Highland Soc. Trans., vol. x.)

SUPPLEMENT. 8016. 8013. 801
8012. Dairies, or milk-houses. “There is great variety in the arrangements of the milk and cheese-houses; but the most frequent form is this:—Between the dwelling apartments and the cow-house, and of the breadth of the house, is a square room, called a milk-house, or rather cellar; it is always three or four steps below the level of the house, paved with brick, and having a door into a cool cheese-well, or stone, and two or four windows, according to size. The milk dishes, or pans, which are daily first hand-scrubbed and washed with boiling hot water, and then with cold, are ranged along the floor, (nearly square,) which may be reached by a dairyman’s steps when he is opened or shut according to the state of the weather, to which particular attention is paid.” (Ibid.)

8013. The cheese-houses are also generally cellars, and adjoining the milk-houses; but in summer the bye-wind gives them a coolness; the floor here is kept quite dry, and doors being open, abundant air is afforded. In winter the windows of the cheese-houses are generally kept shut; and, if any intense frost exists, they put in one of the wooden boxes, containing a pan with burning turf. The cheeses are placed on rows in the wooden shelves. (Ibid.)

8014. The Dutch butter is probably the best butter in the world, the butter being more exquisite in the excellence of the Dutch salt. The butter, though salted, is always well flavoured, and hardly tastes of that acer quality which the muritate or sulphate of magnesia frequently imparts to butter in this country. The men attend to milking and feeding the cows, and the women to making the butter and cheese. As to cleanliness, every dwelling-house is a model and a pattern; the inhabitants seem to vie with each other on this point. The cow-house is pure and clean, not a particle of filth being to be seen in it; the cows are as clean as if they were in a dinner-room; the milk and cheese-houses, and, in short, every part of the house, are free from dust and dirt of any kind; the manure is placed at a convenient distance from the cow-house, behind the house, and every particle is carefully collected together. The whole apartments, even the byre and hay-house, are generally under one roof, and the cleanly system of the admirable arrangements, give that comfort and pleasure which are too often wanting in Scotland.” (Ibid.)

8015. As an example of a Dutch dairy farmery, we copy the plan fig. 1139. In this figure “a” is the kitchen or living-room of the family, during the greater part of the year; “b,” a temporary apartment in which the family take their meals during the warmest weather in summer; “c,” the cow-house, in which the cows are seen from the apartment “d,” a large room used for various purposes; “e,” bed-room; “f,” shed; “g,” dairy; “h,” dairy scullery; “i,” cooler; “k,” a place for drying cheese; and “l,” the dairy proper in the building.” The farmeries in Holland are generally of one story, and thatched with reeds, one immense, lofty roof covering the whole, and the highest part of this roof is in the centre, the hay and straw room. (Ibid. Mr. Alton of Hamilton, who also visited Holland with a view of studying its dairy husbandry, gives a similar account of the Dutch farm-houses.

8017. — 646. An account of Flemish husbandy is given by A. Thompson, Esq., in which the collection and preservation of manure is represented as the chief excellence of the Dutch husbandry. The tanks for liquid manure are built of brick, 4 or 6 together, about 7 ft. deep, and each division from 7 ft. to 10 ft. long, and 6 ft. to 7 ft. wide, and the top is flat or nearly so. These are called “Bekken.” The farmers about Bremen say, “A good plough, neither a good cart, and their hay-fork is like Neptune’s trident.” (Williams Travels, &c.)

8020. — 649. Scurvy or narrow barns are used in many parts of Carniola for hanging buckwheat. 4 N 4
upon. The screen is composed of two upright posts, twenty-feet in height. Through holes in the upright posts, horizontal poles are placed, reaching from one upright to the other. On these poles, the buck-wheat and other kinds of fodder are placed. A narrow roof of boards covers the whole, passing from one upright to the other. The sheaves of buck-wheat are also sometimes fixed on an upright post. (Caldec's Travels, p. 24.)

8021. - 602. Cottars are cultivated in considerable quantities in Carniola and Styria: cut in slices, they are given to the hogs and cows. (Caldec's Travels, vol. i. p. 23.) In Hungary sugar has been lately made from them.

8022. The rural economy of Schleswig, Holstein, and Lunenburgh, has been given at length in the Journals, &c., vol. i. p. 37, and of the agriculture of Denmark and Sweden by James F. W. Johnston, F. R. S. in the same work, vol. iv. p. 196. et seq.

**RUSSIA AND POLAND.**

8023. - 602. Roads in Poland. By far the best specimen of that kind of road usually called macadamised, for want of a more expositive term, is to be found between Warsaw and Kalisz, a distance of thirty-three and a half Polish, or one hundred and fifty six English miles. Throughout this distance it is uniformly hard, level, and as smooth as a billiard table, quite straight, planted with a double row of trees on each side, and with very tolerable inns at each post station. It is doubtful whether a better road is to be found in England; certainly not on the Continent, except, perhaps, between Milan and Cracovia, or even as far as Vicenza. The Warsaw road is perfectly new, and owes its existence to the grand duke Constantine, whose efforts to improve the internal communication of the country in every direction were incessant. One feature of the Polish road in question deserves notice, because it tends to give it the appearance of a carriage-road in a gentleman's park kept in the highest order; namely, the manner in which the sides are dressed all along with green turf, that looks like mossy banks, cut smooth, and perfectly level. This method of building a macadamised road that has been cut through hills, or prominent undulations in the ground, offers, besides its neat appearance, a great advantage; for it prevents, in a great measure, the carrying away of the loose earth and denuding of the roots of trees during heavy rains, both which inconveniences, very injurious to the road itself, take place when the sides are not covered with turf. (Crawfurd's Russia, p. 580.)

8024. British Farmers in Poland. Since the peace of 1814, some Scottish farmers have settled in different parts of Poland, and chiefly in the neighbourhood of Warsaw. The soil and the climate are found much more favourable, both for agriculture and gardening, than might naturally be imagined. Though the winters are more severe than they are at Edinburgh, yet the summers are much warmer, and corn and fruits ripen much sooner and better. The cucumber grows freely, and bears abundantly in the open air during the summer months. The estate or farm of Wilga, on the river of that name, a view of which is given in fig. 1140, consists of 1,800 acres, and was purchased by a near relative of the author in

---

1832. The buildings consist of a dwelling house (a), with a detached kitchen (b), a brewery (c), a distillery (d), a machine for raising water to supply both (e), a corn-mill (f), sheds for feeding cattle (g), an ice-house (h), in which ice is kept above ground by means of thick double walls and doors; and large barns, a three-bing machine, coach-house, stabling and all other offices, including a carpenter's shop and house, blacksmith's shop and house, bailiff's house, &c. Besides these there is a small colony of cottages for the common labourers. Behind the house there are a large garden and orchard, with summer-house green-house, &c., the estate having been the property and residence of a Polish nobleman, considered a man of taste. The situation of this property is about thirty miles from Warsaw, in a flat country, and there is good communication between it and that city, both by land and water. The soil is light in most places, but in others it is loamy. About half the surface is covered with wood, chiefly birch, poplar and Scotch pine, which is felled at stated intervals, and is floated down the Wilga and the Vistula to Warsaw, where it is sold as fuel. The culture pursued on the arable land is the convertible system of - 1. turnips; 2 corn, chiefly barley and wheat; 3 clover; and 4 oats. The turnips and clover are consumed in the feeding-houses by milch cows, or cattle for the butcher. The corn is either ground into flour or malted and brewed into beer, or distilled into spirit; for both of which there is an ample market at Warsaw. Butter and cheese are made, for which there is also a great demand. Pigs are fattened, but the Polish towns being chiefly occupied by Jews, and trade of every kind being chiefly in their hands, it is found that pigs cannot be driven to market, and sold there alive as in Britain; but the carcasses are salted, or cured as bacon, and sold in that state, to Christian consumers. The fattened cattle are sold by private
contract to Jewish dealers, who dispose of them, either to their brethren in Warsaw, Cracow, and other towns in Poland, where they are killed in the manner peculiar to the Jews; or to Christian dealers, either in Poland, Prussia, or Russia. Numbers are sent to Dantzig and other sea-port towns. An unlimited supply of manure may be obtained from Warsaw at present, though it cannot be expected that this will be kept up, but the householders are abundant, but not only in Warsaw, but in any part of the country, and the supply of this manure will, probably, for many years, exceed the demand. A crushing-mill has been, or is about to be, added to the corn or flour-mill on the estate. It is also in contemplation to establish a steam-boat between Wilga and Warsaw, which will add greatly to the rapidity of conveyance between the two places. The flour might then be converted into bread, and the consumption for Christian consumption, slaughtered on the farm; for it is chiefly by manufacturing farm produce, that it can be at all disposed of to advantage in such a country as Poland. The great drawback to farming in Poland is the extremely low price of labourers, who require continual watching both to keep them at work, and from stealing and drinking; but as this has arisen from the harsh treatment to which, as slaves, they have been subjected from their masters through many generations (see § 656.), it may be difficult if not impossible to effect a complete abolition of the evil in the course of a generation.

6829.—672. Food of the peasantry in Russia. Rye bread is the chief support of the peasants in the north of Russia; but, in order to have the rye flour, and to make it last the longer, the inhabitants, who are compelled by necessity to enjoy it, make ground oatmeal, the meal of buck-wheat, and the banks of the field mustard seed (Sinapis arvensis). Brandy is, in general, distilled with a more or less additional quantity of barley, oatmeal, and barley malt; but very seldom from wheat, or bar-built. The Russians also distil brandy from potatoes, cherry berries, and Sörbus aucuparia, at times mixed with maraschino, and they distil, in stills of from damaged wines, prunes, kernels of cherry-stones, and wild almonds (Amgładus ramosus). Some of the distillers make use of the skin and stalks of pressed grapes, raisins, and the waste in sugar refineries, with which they make good brandy. To the worst and common sorts of brandy belongs the dram of Kamtschatka, of Heracleum Spondyllum, and another used by the Kalmucks, and the cattle of mare’s milk, which is spirituous, but rather of a disagreeable flavour. (Comm. Board Agr., vol. i.)

AGRICULTURE IN LIVONIA. The country, before reaching Volhina, offers a tolerable specimen of the foregoing, both in the shape of forests, and in the paintings of the village scenery. The forests are met with here and there, succeeded by corn-fields; barren heaths; farm-houses, consisting of one or two wooden buildings, and a yard, in tolerably good condition; small horses, and diminutive horned cattle, are always kept; a kid of goats, which are, in consequence of the language, and donkey, and mule from the farm-houses from intrusion; and extensive buildings serving as granaries to hold the crops. These are the most prominent agricultural features of the country. The Livonians have the reputation of being good farmers. (Gregorovius’s Russia, p. 382.)

6830. Agricultural production in Livonia. The hop is indigenous in the district of Petersburg; a few are also cultivated in gardens, and the crop gathered the end of September. Hemp is sown about the middle of May, and pulled in the beginning of September. Flax is sown in the beginning of June, and pulled up in the same month or the beginning of July. Both these plants are grown on private use. Red clover is sown along with barley and oats, and cut the following year, about the end of June, and the second in September; the plants are frequently destroyed by the early frosts. The farinaceous plants grown in the district of Petersburg are the following:—Some winter wheat upon good soil, and in the first part of the beginning of November, is raised in the beginning of April; and the last end of August; in the middle of March, is raised in the beginning and middle of August. Spring rye is sown upon high and sandy ground in the beginning of May, and reaped the latter end of August. Barley is sown in the beginning and middle of May, and reaped about the middle of August. Other plants are sown the latter end of April and beginning of May, and reaped from the middle of August to the beginning of September. Buck-wheat is sown upon high sandy and in the month of May, and reaped in the beginning and middle of September. No objectionable plants are cultivated, except the saffron and the white mustard in a few gardens. The following are the leguminous plants of the same district:—White and gray peas are sown in the beginning of May, gathered green the latter end of July, and ripe the latter end of August. Beans are sown in the beginning of May, and reaped in the middle of August: French beans are sown in gardens, but they seldom do much good. (Comm. Board Agr., vol. i.)

SWEDEN.

6828.—688. General appearance of the country in Sweden. A bishop of Bergen is said to have given the name of Northern Italy to some districts of Norway and Sweden. The pine forests are very beautiful, especially when the pale green of the young shoots contrasts with the darker foliage. From the appearance of these trees, it is easy to perceive that it is the home of the most noble trees in existence, the beauty of the roots of the pine and the mountain ash, through islands, contribute to the splitting of the rocks. The Swedish milestones are raised on plinths to keep them above the snow. The roads, winding through extensive forests, are practically in the extreme. (Brooke’s Travels, p. 106.)

6829.—693. The cottages of the peasants in Norway have double fronts. This additional protection renders them warm and secure against the blasts of winter. The manner of building these cottages is the same as in Sweden; and on the roof of each, a luxuriant crop of grass was generally growing, though some of the thatch were not thick enough to cover three large fragments of rock, to secure the whole from being blown away by the winter storms. (Brooke’s Travels, p. 105.)

6830.—704. Stakes for drying newly-cut corn are also used in Sweden. They are generally made of young trees and a half a dish long, and a half an inch thick, and are placed in the bottom. Both ends are pointed, and the thick end is let into the soil by the aid of an iron crowbar. The first sheaf is put on the stake with the root ends of the corn downwards, and the other sheaves, to the number of fifteen or sixteen, are placed in an inclining position. (Quart. Jorn. Agr., vol. iii. p. 628., and Professor Johnston in Jornal. A. N. E., vol. iv. p. 156.)

BRITAIN.

6901.—690. The progress of agriculture in Britain, more especially in England, since the second edition of this Encyclopaedia was published in 1831, has been singularly rapid; though it must be acknowledged that it has hitherto been more in the direction of discussion than of actual improved practices; the introduction of the latter require time. The first great stimulus to agricultural discussion in England appears to have been given by the Report to the Agricultural Committee by Mr. Shaw Lefevre, which was printed in 1836. In this Report the frequent drain system, introduced in Scotland by Mr. Smollett, was proved capable of excellent effects as compared with the system in general use in the country, and raising it in a short time to a par with the very best soils. According to Mr. Lefevre’s idea, if this system were applied, whether with or without a corn law, the produce of Britain would become so abundant, that there would be no danger of prices rising for half a century. Mr. Lefevre considers the British agriculturist to accede to a total repeal of the corn laws, and to stand on the field of free competition with all the world; trusting to his improved skill and improved modes, to his capital, and to the altitude of the soils of his country for improvement, to enable him to do so.
ENCYCLOPAEDIA SUPPLEMENT.

In two years after the publication of this report, the Royal Agricultural Society of England was formed; partly from the increasing interest taken in agriculture by the landed proprietors, but principally from their having observed and remarked on the great good effected by the Highland and Agricultural Society of Scotland.

The idea of the Agricultural Society of England was first suggested by Lord Spencer at the dinner after the show of the Smithfield Club in the beginning of 1832, and a meeting was held for that purpose on the 9th of May following, when the foundation of the Society was laid. Its progress since has been uninterrupted, and it has, in three years, become one of the most active and effectual of the numerous counties upwards of 80, which the landed proprietors of England. The society holds annual meetings in different parts of England, as the High-

land Society does in Scotland; and its journal, which is published quarterly, contains a great number of valuable communications from scientific men and experimental farmers, including all the great landed proprietors of England. It has called forth several eminent chemists who have directed their attention to agriculture; and in this the British Association have taken a prominent part. It is to this Association that we owe the volumes of "Lectures to the Farmers of Suffolk, 1832, 8vo." by which the same experiment may be repeated in any number of places all over the country. Excellent works on the Chemistry of Agriculture have been published by Professor Johnston, of Durham, Mr. Solly, the Professor of Chemistry to the Horticultural Society; and important essays or treatises on some subjects with reference to Agriculture, by Professor Daubeny, Dr. Madden, Dr. Lyon Playfair, Mr. Trimmer, Mr. Johnson, Mr. Lumbard, and others; and the stimulus given to this subject and the society, which has been given an impetus to improvement, that there can be no doubt of its rapid progress for a long period to come.

In Scotland, though the agriculture is far in advance of that of England, yet advantage has been taken of the information which has been received in the country, and many domestic animals, has received general attention, and the consequence has been great improvement in this department.

Ireland has established the Royal Agricultural Society, which continues the exertions begun in 1832, and has contributed more to the improvement of the agriculture of small farms in Ireland than Mr. Blacker, of Armagh, whose essays on the subject ought to be in the hands of every proprietor in Ireland. (See Catalogue, and also Q. J. A., vol. v., p. 386.)

The average of the several years, as it may be supposed, considerable progress has been made since 1831. The Mark Lane Express is the most popular farmer's newspaper in England; but we have also the New Farmer's Journal. There is no paper of the kind in Scotland; but in Ireland there is "The Farmer's Gazette, and Journal of Practical Horticulture," a very excellent weekly paper. In Ireland, the Farmer's Magazine, the papers in which generally appear first in the Mark Lane Express; the British Farmer's Magazine, and the Journal of the Agricultural Society of England. The only agricultural periodical in Scotland is the Quarterly Journal of Agriculture, which continues to maintain a high reputation. For the other works published since 1831, we must refer to the Catalogue in continuation of that given in the Bibliography of British Agriculture, p. 1205. As this Catalogue is arranged in the order in which the works were published, a glance over it will form a very good chronological history of agriculture from 1831 to the present time.

AMATIC TURKEY.

On the agriculture of Asia Minor some interesting notices will be found in the Journal of the Geographical Society, vol. x. It appears that on the banks of the Lake Van, the drill husbandry has been practised from time immemorial, with rude, but yet ingenious implements.

PERSEA.

The general appearance of the country in Persia is characterised by its chains of rocky mountains, its large and riverless valleys, and its stunted trees. The western provinces form an extensive table land, which rises from a lower plain, and is interspersed with numerous clusters of hill, chains of rocky mountains, and barren deserts. The lower ground, under the name of Dastizistan, or the level country, exhibits a succession of sandy wastes, where the eye is occasionally relieved by a dark plantation of date trees, and a few patches of corn, in such places as are blessed with a fresh-water rivulet or a copious well. On the banks of the Tigris this tract becomes more fertile. Wherever water abounds, vegetation is most luxuriant; but the country generally suffers from excessive drought. The mountains present masses of grey rock, and the only trees that are found in abundance are the tall poplar and stately chinar (Platanus orientalis), and the fruit trees which surround every havel. These hovels are clean and comfortable; and wages are high, while food is cheap. (Fraser's Persia, Edin. Cab. Lib., vol. xx.)

INDIA.

To give some idea of the present state of agriculture in India, Mr. W. Carer, one of the missionaries, states, in the Transactions of the Agricultural and Horticultural Society of India, vol. ii. part i., that in many parts of the country, the same crops are raised year after year; hay is never cut till the grass has died or withered on the ground; scientific rotation of crops is a subject to which Indian cultivators are strangers; and the manure produced by animals is not used as fuel. Nevertheless, the attempt to improve the condition of the agricultural society, though there is every reason to believe that all the animals used in the husbandry of Europe are capable of as high a degree of improvement in India as they are in more temperate regions. The quantity of waste lands in India is said to be so large as to almost exceed belief. Extensive tracts on the banks of the Ganges and Goomtur are, basaltic, with so many new lights on broad acres of grass, seldom turned to any useful account. During the rainy season, these tracts are the haunts of wild buffaloes, which in the night come up from them and devour the crops of rice on the high lands. In the cold season wild sheep, goats, and other noisy animals, with the buffaloes in occupying these extensive tracts of alluvial soil; which, though now so pernicious, might, by embanking and draining, become the richest lands in the country, and contribute greatly to the improvement of the climate. Similar observations might be made respecting the immense tracts of land lying waste on nothing whatever to civilise man, but, on the contrary, proving a nuisance to the surrounding districts by affording a shelter to noxious animals. The oppression of landowners, and petty officers, on the cultivator is so great that in some parts of the country no farmer can reasonably promise himself suco-
HISTORY OF AGRICULTURE.

ridy for a single night. "Thus," concludes Mr. Carey, "one of the finest countries in the world, comprising almost every variety of climate and situation, diversified by hills and valleys, intersected in every part by streams (most of which are navigable six months in the year, and some of them through the whole year), the situation of the lands, under a proper management, (and a fair market,) is, as far as respects its agricultural interests, in a state the most abject and degraded." (p. 10.) This is a most forbidding picture; but it is incident to all countries in a particular stage of their progress in civilisation. Time was when the low districts of England were ravaged by the wolves and bears from the English Channel; but in latter times the rivers were merely regarded as nuisances, or at least greatly injured, by floods. As to oppression by superiors, and thievish from others, there will always be abundance of such evils, till mankind are brought to something like equalisation in point of freedom. (Harrington's Essay.) short, the mass of society have been kept in a state of servitude. (Trans. Agr. Soc. of India.) The potato has at length been extensively introduced into India, and as good potatoes to be had in Calcutta as in London. Baron Hugel introduced them into Cashmere and Lick-tie Tibet. (G. C. P. H. iv. p. 5.) A copious account of the agriculture of Hindostan, will be found in the G. J. A., vol. viii. ix. x. xi.

AUSTRALIA.

589—1037. The whole territory of New South Wales. Dr. Lang, writing in 1834, informs us, "is divided, like that of Great Britain, into counties and parishes; but these divisions are scarcely ever referred to in the common intercourse of colonial life. Except in government deeds or legal documents, the grand natural divisions of the country are the only ones recognised by the colonists." The Grand Division, or Department, of the Colony, of Hunter's River, of Hawkesbury, of Bathurst, of the Hawkesbury, is "for the most part merely scratched; and nothing like a proper rotation of crops is ever dreamt of. Wheat, year after year, for twenty years together, and sometimes wheat and maize in succession off the same ground, during the same year, is the Sangrado system of husbandry that prevails on the Hunter. The harvest of wheat is let out in lease from the farmer who produces the wheat. "Dairies are frequent throughout this extensive district; and large quantities of butter and cheese, of superior quality, are forwarded regularly by the steam-boats to Sydney." The Best plains of the Barwon, the lower part of the Sturt, and the river Sheen, are generally good land. This may be considered the wool district. The cultivated land of the Argyle district is almost all in pasture, but there are interspersed extensive tracts of the most barren country imaginable. The district of the Illawarra consists of a narrow strip of arable land of the first quality, let out to "small settlement," much claim, etc., for the Sydney market. This is watered by the Georges, Barcoo, and Shoalhaven, watered to the capital by water in small coaling vessels." This is also the timber district, great numbers of the red and white cedar trees growing here, and that wood being generally used for cabinet and joiners' work. There are several extensive tracts of common land, which cannot be properly classed in any of the above-named districts; and a very great extent of country remains unexplored. The rich alluvial land on the banks of rivers is called interland. It is productive, but is difficult to clear. Norfolk Island has a soil of the richest vegetable mould, even to the tops of the highest hills, and appears well adapted for the culture of coffee, if not sugar. It is now (1834) occupied as a penal settlement for the colony of New South Wales. (Dr. Lang's Historical and Statistical Account of New South Wales, vol. i.)

594. The soil of daughters of both Haplox, in 1833, Stuart tells us, excluded from the 32nd and the 33rd parallel of latitude. The population of the colony is said to consist of 45,000 free settlers, and 25,000 convicts. Its imports, in the year ending January, in 1833, amounted to 602,632l., of which 144,753l. was the value of commodities imported from foreign countries; the rest being the produce of British colonies. The exports were valued at 3,434l., of which 81,569l. consisted of British and foreign merchandise re-exported, and the remainder was the produce of the colony, the New Zealand fisheries, and the South Sea Islands. The chief articles of export, which were shipped to the mother country annually, were gaud and black ovals, wool, 149,942l.; and wool, 1,121,150 lbs , value 73,556l. In 1831, no less than 150 vessels entered the harbour of Port Jackson from foreign ports, the amount of their tonnage being 31,299 tons. (Stuart's Expeditions, vol. i.)

594.1—1038. The mineral productions. Marble of a good quality, and which takes a beautiful polish, has been obtained in Argyle. In one part of its course, Hunter's River flows for a considerable distance over rocks of Jasper; and beautiful agates, opal, and chalcedony, besides innumerable petrifications, are found on its banks. (Hist. and Sta. of New South Wales, sec.)

842—1040. Natural productions of New Holland. A peculiar character is given to the woods of the extralateral parts of the country, and to the woods of Van Diemen's Land, by the species of trees that grow in them, and the leaves of these trees are of a general colour, and bear the same position, and a similar aspect on both surfaces. These surfaces, a close inspection teaches, are decorated, by a reticulation of the fine veins of the leaf, into numerous small compartments or areolae, within each of which, on one face of the leaf, and very generally on both faces, is lodged a minute gland. (See Bell, Trans. Bot. Soc. New South Wales, sec.)

810.3. The vegetable productions of New Holland. Some of the most common trees in the neighbourhood of Sydney are several of the different kinds of Eucalyptus; what is there generally called the honey-suckle (Angophora floribunda), the tree that bears the black, white, or purple seedberry (Melaleuca); and the grass tree (Xanthorrhoea arborescens). The last is particularly beautiful. There are also the broot (Jacksonoa speciosa), which is called the dogwood at Port Jackson, and the wood of which is very difficult to burn, and the tea tree (Melaleuca linariifolia). The name of tea tree is given...
The wood of trees of this genus is very durable; as a proof of which, Dr. Lang informs us that a stump of a species of Eucalyptus (blue gum tree) remained quite sound for thirty-five years in the ground, after having been cut down. When it was necessary to remove it, it took a fortnight to burn out the root. The circumstance of this trunk remaining quite sound for such a great length of time is very remarkable; and reminds us of what Dutrochet states respecting the stump and roots of the silver fir (Gard. Mag., vol. x. p. 408.); viz., that they will continue to live, and even grow, during a great number of years after the tree has been felled. (Lang's Hist. and Statist. Account.)

8044—1841. Agriculture in Australia appears to be making considerable advances, from the more frequent influx than formerly of emigrants with capital. Some Scotch farmers have settled in the interior of New Holland; a good many have located themselves in Van Diemen's Land, and there are some even on the Swan River. In 1838, the Cashmere goat was imported into the colony by Mr. Riley, and about the same time a German gardener, that Mr. Riley took with him from England, established vineyards in different parts of the country, which, from accounts received in 1834, have already produced wine. (See Gard. Mag., vol. x. p. 159.)

8045. The principal agricultural products of New South Wales are wheat and maize. The cost of clearing heavily timbered alluvial land is about $6 an acre, but sometimes a single crop of maize clears the expense. The return of wheat varies from 13 to 40 bushels an acre, and in the Argyle district it has reached 45 bushels; but the system of husbandry is, generally speaking, wretched in the extreme. The staple article of Australian produce is wool, of which Dr. Lang says, 1,515,156 lbs., and Sturt, 2,500,000 lbs., were exported in 1833. It is generally supposed that John Macarthur, Esq., was the first to introduce fine-wooled sheep into the territory; and, though the honour is also claimed by another individual, there is no doubt that Mr. Macarthur had the merit of having demonstrated their adaptation to the climate, and the capability of the colony to produce wool to almost any extent. This has been effected in comparatively a very short space of time. About 1792, Mr. Macarthur commenced sheep farming, and in a year or two, he had an opportunity of crossing his coarse-fleeced sheep with merino blood. So prolific was the mixed breed, that in ten years, a flock, originally consisting of not more than seventy Bengal sheep, had increased to 4,000. In 1803, Mr. Macarthur went to England, carrying samples of his wool, which was so much approved of by a committee of manufacturers, that government were induced to encourage him in his attempts to produce fine wool in the colony, by directing that he should receive a grant of land for that purpose, in the low pastures, which is now named the district of Cambden. In 1806, Mr. Macarthur returned to New South Wales with two ewes and three rams, purchased by him from the merino flock of George III; his flock was removed to the low pastures, and since that period, the wool of New South
Wales has been rapidly increasing in value in the home market. (Dr. Lang's Hist. and Statist. Ac-
count, and Murr. on the Aust. Interior of Austr.)

8046. Fruits and other vegetable products cultivated in the colony of New South Wales. Vine-

| 8047.—1042. As a country for colonists. During Sir Thomas Brisbane's administration, any respec-
| tive person, who pledged himself to government to maintain and employ ten or twenty convict secre-
| taries, could obtain 100 acres for each such servant. This occasioned a great demand for convict labourers; and such convicts were shipped settled in to facilitate them, there was, during the government of General Darling, "applications for more veteran than 2000, who were unsatisfied at the office of the principal superintend of convicts." There is no doubt that New South Wales is an excellent country for the agriculturist; but it is subject to some drawbacks. A season of drought, which continued three years, began in 1827, and it appeared from the statements of old
| natives, that the country was subject to periodical visitations of that nature. It is also subject to im-
| minations, particularly from the Hawkesbury River. In the imperfect state of husbandry throughout the
| country and the fertility of the soil, much may, however, be done by an experienced agriculturist. For
| eight months in the year, from March to November, the climate is delightful; but during the Australian
| summer, the heat is considerable. The most unpleasant part of the year is during the prevalence of the
| hot winds. These winds occur on an average four times every summer, and continue from twenty-
| four to thirty-six hours at a time; the atmosphere is kept in constant motion by a current of air from a
| fortress, and the thermometer generally standing at from 90° to 100°, and sometimes even reaching 120° of
| Tenrenheit. The extreme dryness of the air, however, prevents this degree of heat from being intolerable and
| is more mitigated by the coolness of the night. In this hot climate, the soil from the southward, and very often by a shower of hail. (Vol. ii. p. 186.) Very few persons live to attain old age; but they generally enjoy excellent health and spirits while they do live. In short, observes Dr. Lang, "the lamp of life in the salubrious climate of New South Wales is like a taper in a bottle. It burns more bright for a short period of time, than if placed in a vault, but is immediately
| sooner extinguished." To persons possessing property to the amount of from 2000l. to 5000l. New South Wales presents a most eligible prospect for effecting a comfortable settlement. They may put one-third of their fortune, on excellent land, and every year may add 1000 acres of land at 5s. an acre (the selling price in 1830), but will be amply sufficient to stock it. (Lang's Hist. and Statist. Account, vol. ii. p. 200.)

| History of Agriculture. 1093

| EGYPT.

| 8051.—1077. Egypt, under the government of the present pasha, is undergoing extensive political im-
| provements, among which agriculture, Mr. St. John observes, is not altogether forgotten. The culture
| of cotton has been commenced on a large scale by government; and an extensive tract of country round
| Cairo, which was long rendered useless by profligate crowds of rubbish, many of them exceeding
| seventy feet in height, has been cleared, the mounds having been levelled, and planted with olive trees,
| with tea and coffee, which has been introduced from India, near Cairo as well as in its native country. The
| mango, the pine-apple, and other tropical fruits, have been tried; and there is an English garden of naturalisation, under the direction of Mr. Trul, an English botanist. The idea is that, if the present
| political state of the Egyptian government be continued for another generation, the face of the country, and the condition of its inhabitants, will be entirely changed. Nature has supplied an excellent soil, and abundance of water, under a climate sufficiently hot to mature the fruits of tropical regions, and yet not too hot for them to be profitably cultivated. (Egypt and Mahometan Asia, 413.) In Dr. Bowring's Report on Egypt, presented to parliament in 1849, that country is shown to be
| making gigantic strides in civilisation, through the efforts of the present viceroy, Mahomet Ali. Agriculture is improving, though not very rapidly. The principal agricultural produce of the country
| is clover, corn, beans, barley, peas, and various other seeds. Watering is an essential element of culture.
and by means of it the soil, which in many places is excellent of itself, is made to produce enormous crops. The various details of Egyptian agriculture, as extracted from Dr. Brough's Report, will be found in the "Gardener's Magazine" for 1840, p. 615 to 635.

Morocco.

Agriculture in Morocco. The farmers plough and sow at the same time. The ploughing is performed by one man, who, while he guides the plough, which has a single handle, with his right hand, holds the reins, which are made of the palmetto twisted, and a long, thin, pointed stick to goad the oxen with, in his left hand. When he has ploughed the land he leaves the right hand on the plough, turns it to the right hand, and harrows it in by passing the plough again over the surface, the furrows being straight, narrow, and very shallow, without any ridge. The ploughshare has merely a simple tip of iron, which is taken off when the husbandman ceases to work, to prevent its being stolen. (Brooke's Travel in Spain and Morocco, vol. i. p. 363.) Some account of the progress of agriculture in Algiers will be found in the G. C. 1842, p. 67.

Cape of Good Hope.

At the close of 1824, when this new settlement was beginning to dissolve, the commissioners of enquiry removed certain political evils, and the country at once commenced a march of success, which John Cundliffe Chase believes "the most unparalleled in the history of colonisation." In August, 1833, the Caffre trade, chiefly in ivory, amounted to about 34,000l. annually; and the exports increased from 32,272l. their amount in 1829, to 51,290l. their amount in 1832. Hides, horns, skins, tallow, and ivory, formed the principal items. Cultivation is extended. Oats, barley, and oat-hay are the chief commodities; wheat has also been raised, and Indian corn, fruit, and vegetables grow most luxuriantly. Cattle, sheep, and horses are abundant, and every necessary of life is extremely cheap. There are about 25,000 sheep, the weight of which, of 1s. per pound. Graham's Town has increased from 22 houses to 600; and eight villages, eleven places of worship, and fifteen schools have been built. Hat, blanket, and the manufactories, numerous limekilns, three water and six wind mills, 19 breweries, and two breweries, and two breweries, have been established. There is an infant school, a savings bank, a public reading room, and a commercial hall. A newspaper was commenced in January, 1832, and it is prospering. The population, in 1833, was 9513; and, as a proof that the country is favourable to human life, only 21 out of 248 persons, who arrived in 1829, had died in 1830, of which 12 were men, nearly five of which were those of failure and distress. From what has been related, it may be seen, whether success has attended the efforts of the immigrants or not, their only difficulty, in as far as my own knowledge goes, is that of a want of labourers to grow the crops in the harvest modes of obtaining it; and, as a proof of this want, I refer to the many and frequent appeals to the home government, successively made since 1825, for a new emigration." (The Cape of Good Hope Lit. Gaz., vol. iii. p. 182.)

AMERICA.

Climate of the Canadas. John Young asserts, "that, 2000 years since, the climate of Europe was precisely similar to that of British America at the present day; in support of which he quotes many authors of antiquity. He attributes the change, first, to the extirpation of the forests and the draining of the swamps; secondly, to the increase of population, and consequent result of animal life, which have taken refuge among them. They are also indebted to them for some seed and kernel fruits. The territories of the United States, with regard to agriculture, may be divided into two parts, perfectly distinct from each other. The lands bordering on the Atlantic are generally inhabited by the French; the others on the other side of the Alleghanies, in the basins of the St. Lawrence and the Mississippi, are not exceeded by the best lands in Europe; and have, besides, the advantage of being nearly all virgin, and easily cultivated. Vegetation is hardy, but prompt, which is occasioned by the heat of the sun (bony heat of the United States), and as it is as quick as it is in any part of Europe. Sugar has been extracted from the maize, to such an extent as to become an article of commerce; and Mr. Collman, who has been deputed by the state of Massachusetts to the Royal Agricultural Society, that the process of extracting sugar from the maize might be carried out in England with as much success as in America. (Morn. Chron., June 22d, 1843.)

Emigration to British America. Mr. Ferguson, who visited Canada in 1831, says, "that Upper Canada is blessed with all the solid appearance of human happiness, independence, and comfort." The notes of this gentleman are given at length in the Quarterly Journal of Agriculture, vol. v. p. 124, 1835.) The country is supposed to be divided into two emigrant divisions by all emigrant guides, by John M'Gregor, Esq., published in 1831, the British possessions in North America are stated to be the Island of Newfoundland, Cape Breton, and Prince Edward Island; the province of Nova Scotia, New Brunswick, and the Canadas; the region of Labrador and the northern parts of the North Atlantic, or the Atlantic Archipelago, to the West-India Highlands of Scotland, and is chiefly adapted for the rearing of cattle and sheep. Prince Edward Island possesses an excellent climate and soil, and is, taken altogether, a most desirable spot for emigrants. The society in the island is good, and the inhabitants those of all nations from all quarters, but particularly from Scotland. New Brunswick is a small island, peopled by between twenty-five and thirty thousand souls, chiefly from the Western Highlands of Scotland. The climate, though humid, is salubrious; the general aspect of the country romantic and mountainous, and fecundated with forests and woods; and the valleys contain extensive tracts of excellent land. Nova Scotia is an extensive country, fitted to receive "thousands, perhaps millions, of emigrants." The winters are severe, but the air at that season is generally dry. This peninsula abounds with extensive fields of coal, with ironstone, with gypsum, and with coal. It is believed, with rich, salt, New Brunswick has a climate of particular value to the constitution of Britons. The country is covered with immense forests of evergreen and deciduous trees, and it is everywhere intersected by rivers fit for nav-
gation. Coal, iron, gypsum, and sandstone abound. The Canadas include an extensive territory, with a climate which is on the whole subarctic. The thermometer, in summer, rises as high as 80° in the shade. The winter in Lower Canada is two months shorter than that of Upper Canada. The geology of Canada is little known; the principal rocks appear to be trap and limestone. There are soils of every description, but the largest tracts are either alluvial, or of a lighter character. The climate has a decided influence on the territory which has been inhabited, and there is no doubt that it does not consider as suitable to emigrants. We can only refer the reader, who is desirous of emigrating, to Mr. McGregor's book; or to a very copious abstract of it which will be found in the Quarterly Journal of Agriculture, vol. iii. p. 886, to 890. 885—1197. The culture of wheat in the West India Islands may be mentioned as a comparatively new agricultural feature. The kinds which succeed best are the summer varieties, which have been cultivated to advantage in Jamaica, Barbadoes, and several other islands. Great exertions have been made to introduce these and other varieties into these islands from Europe, and to make known the success which has attended their culture by Dr. Hamilton of Plymouth. (See Gard. Mag., and Gard. Chron.)

PART II.

AGRICULTURE CONSIDERED AS A SCIENCE AND AS AN ART. (p. 208.)

8959.—1295. The present state of agricultural science has been treated of in a prize Essay by Dr. Madden, published in the Highland Society's Transactions in March 1842, from which, as taking the latest and most comprehensive view of the subject, we submit the following abridgment:

1. Should agriculture be regarded as a science? What has science done for agriculture? The science of agriculture has been investigated by an extremely limited number of individuals, and this chiefly since the commencement of the present century; that a great drawback to the advance of agricultural science is to be found in the want of confidence in it of practical men, and that among practical men there is a great want of scientific knowledge.

"If by the question, 'What has science hitherto done for agriculture?' we are to understand which of the new improvements owe their origin to scientific investigation, we feel obliged to confess that as yet we know but little of it. But if, on the contrary, we are to understand it in the wider sense, as requiring an account of what science has effected towards establishing agriculture upon a sure basis, the farmer may be enabled to apply his practical knowledge in whatever situation he may be placed, and will be at once capable of determining what changes in his arrangements, &c., are necessary if called upon to change his farm, so that his operations will no longer be so much the sport of chance that each farmer can be considered as knowing only the treatment suited for his own farm, we can confidently assert that much, very much has been accomplished; and although there is no point upon which we are assured our knowledge can be increased to the same extent in some state of science which has not already thrown sufficient light to enable those, who are at all capable of appreciating her services, to derive great benefit and direction in cases of difficulty." To prove this, he takes a general view of what part of agricultural science has affected the heads of 1. Soil; 2. Effects of Vegetation upon soil; 3. The Art of Culture, and 4. The Economy of Husbandry.

8960. 1. Soil. Science has already proved, in the most satisfactory manner, the following circumstances regarding soil:—

1. In order that it may be fertile, it must contain all the mineral matters found in the ashes of the plants destined to be cultivated upon it, in such a condition as to be available by the plants, and in sufficient quantity to enable the supply to be kept up by some economical mode of cultivation. 2. The necessity of this condition depends upon the well-established fact, that plants cannot make for themselves any of the elementary substances which they contain, but are only capable of changing the form in which these are combined with one another. Thus, the organic portion of plants, or that which is destructible by fire, is composed of carbon, hydrogen, and nitrogen, and with the addition of oxygen, carbonic acid, water, and carbonation; and finally of carbon, oxygen, carbonic acid, water, and carbonation. Now plants cannot produce any of these four substances under any circumstances whatever; but if they are supplied with them, in almost any state of combination, they can, by their vital processes convert them into starch, gum, wool, fibre, or whatever else they may require. The same is the case with the constituents of the weeds, their requisites must be supplied, or the weeds will arise in every state of combination, and then they will be able to produce for themselves the particular compound which they require. 3. Mr. D. Madden admits, that a considerable increase of knowledge is required among farmers before this part of agricultural science can be brought to perfection; though he believes that much of the future progress of agriculture depends upon increased knowledge in this department of agricultural chemistry.

8962. 2. Soil must consist of a due admixture of impalpable matter and larger sized particles, so that it may be both porous and easily permeable by air and moisture, whilst, at the same time, there is a sufficient supply of matter in a state capable of undergoing chemical changes. All the useful organic matter of soil is in a combination with the impalpable earths which it contains; though the larger particles are necessary for the admission of air and water. Till these larger particles are reduced to powder, they exert no direct influence whatever upon the vegetation of the soil of which they form a part. 4. Soil must contain a sufficient supply of organic matter mingled with it in a state capable of decomposition, by the action of our own agents. In general, the quantity of vegetable and animal matter in a soil is a direct index of its fertility.

8964—4. Soil, to be fit for profitable cultivation, must be free from any mineral substance which is destructive of fertility. This is a case in which no farmer will doubt the utility of chemical knowledge; thus, if the injurious matter be an acid or a soluble salt of iron, it may be neutralised by lime; or if it should be some compound of magnesia, it may be rendered innocuous by exposure to the atmosphere. 5. Soil must be capable of being reduced to a sufficiently fine tilth, without an undue amount of labour, so as to render that its cultural mode of treatment. 6. Soil for a good farm must either be naturally capable of letting off any superabundance of water, or it must be capable of being made to do so artificially by draining. The advantages of draining a soil naturally moist can hardly be over rated. It not only alleviates the pressure of plants on the roots, but regulates the temperature of the atmosphere, so that a drained soil will always be found to produce an earlier vegetation than the same soil undrained.

8967—7. Soil, to be useful to the cultivator, must possess a structure which will allow the decomposition of organic matter without reducing it to proceed at a regular rate, being neither so slow as to keep it too long fresh. Humus gravel, coarse sand, or strong clay, are to be improved by the addition of soils of an opposite texture, by the use of suitable manures, and by appropriate mechanical treatment, such as exposing burning clays to the frost of winter, or the intense heat of summer, compressing loose gravels or sands, &c.

8968...8. The situation of soil must be such as to admit of all the operations of husbandry being per-
formed in a proper manner, without occupying too much time; and the climate must permit of the plants arriving at perfection.

969. In order that soil may be advantageously subjected to continued cropping, the farmer must keep up its essential qualities by ploughing, harrowing, and any other operations necessary to pulverize it.

970. — 10. Soil intended for continued cultivation must have its supply of organic matter, and part also of its mineral ingredients, renewed by returning it, from time to time, in the shape of manure, what has been removed from it in the form of crops.

971. — 11. The condition, as well as the composition, of the manure, must be attended to; because soil under cultivation is preserved from warming by it, at certain periods, substances requisite for fermentation.

“Numerous facts tend to prove that the success of many crops depends upon the existence of fermenting matter in the soil, and that however rich it may be in other respects, these crops can only be advantageously cultivated when an addition of manure is made. This is particularly the case with turnips. We have found the richest soil will bear but an indifferently good crop; while with manure, very poor soil, if it be not too wet, will at all times give a good return. Science has not yet been able to account for this satisfactorily, although many of its votaries are willing to acknowledge its truth; and it is obvious that an acquaintance with the fact that the greatest value is got by the farmer in his arrangements, for he will by course of applying dung when he intends to raise a crop requiring the existence of fermenting matter, and thus insure its success, while he does no injury to the following crops, whose growth is, to a certain extent, less dependent on the condition of the soil.”

972. — 12. To correct any natural faults which the soil may possess, it must be subjected to various processes which have been proved by experience to cure the faults in question. “The chief of these are: draining, liming, and burning.”

973. Draining. — The importance of draining, and especially of furrow draining, is now very generally understood, and the practice is so widely extended that it is in some danger of causing the advantage of deep draining to be overlooked. “A soil which is naturally capable of easily getting quit of surface-water, may be rendered quite marshy by the existence of a spring. Now, to furrow-drain a field of this kind would, in many cases, be absurd, for in all probability the spring would be missed, and after all the expense of laying the drains, the soil would remain almost as wet as at the first. The proper treatment, in such an instance, is to search for the rise of the spring in the highest part of the field, and having found it, one good drain will frequently have the effect of draining the whole field. The reason is, that the water rises from both causes conjointly, viz., spring and surface-water, it is obvious, that however free an exit be given to the spring, the soil cannot be made dry without having recourse to furrow-draining to a greater or less extent.”

974. Liming. — “Lime has three distinct great effects, in addition to several minor ones: 1st; it greatly hastens the decomposition of the organic matter in the soil, and in doing so renders it much more valuable to the crops. 2d. It alters the texture of the soil to a certain extent, proportionate to the quantity applied. 3d. It adds, of course, calcareous matter to the soil. From both these considerations, it is directly applicable to all cases where there is an accumulation of undecomposed vegetable matter, as in poor old pasture, heath, peat, moss, moorland, and the like.” Lime is not required in soils which are poor for winter crops, nor in soils that are calcareous. Limed does not add directly to the fertility of the soil, but only increases it, by calling into activity organic matter. Lime exhausts the soil by bringing the organic matter which it contains into action; and hence many lands will yield for a year or two after liming, better than they did before; but after this time, the productive powers fall as much below the natural standard, as they had been artificially raised above it by liming.

975. Burning. — “The immediate beneficial effects of this process are fourfold. 1st, It destroys a large quantity of organic matter. 2d. It alters entirely the texture of the portion of the soil through which the heat is directly applied. 3d. It introduces a certain alkaline earth, contained in the burnt portion, and dissolved. By means of these alkalies it acts upon the remaining organic matter of the soil exactly as lime does. To arrive at a just conclusion as to the true economical merits of this process, we must bear all these four facts in mind: 1st. As it destroys a large quantity of organic matter, if of course exhausts the soil to the extent of the quantity destroyed; this is, therefore, in one respect, a disadvantage. 2d. As it completely alters the texture of the portion burnt, viz., by giving to the clay the feeling and texture of sand, we must consider how far this would be advantageous to the soil. 3d. and 4th. As it produces alkalies which acts on the vegetable matter of the soil, and the organic matter; in both cases, the destruction of organic matter, it becomes of importance to decide whether the soil will bear the deterioration without a real loss of value.”

976. — 11. The Effects of Vegetation upon Soil. — Science explains, more or less satisfactorily, the causes of the following facts.

977. — 1. Unculti ved soil, however rich, becomes gradually less and less fertile until it has attained the condition of moor or marsh.

978. — 2. Unculti ved soil retains its luxuriance for the greatest length of time, when covered with forest trees and other large vegetables.

979. — 3. Land not disturbed by the plough produces successive crops of different kinds, or, in other words, a sort of natural rotation is, to a certain extent, maintained.

980. — 4. On cultivated land, when any species of plant disappears, its place is supplied by one of less value as an article of food, and thus the richest pasture comes in time to produce only the coarsest and most worthless species of grass.

981. — 5. Although the natural produce of unculti ved soil thus uniformly decreases in value, the soil itself becomes progressively richer; so that when brought under the plough, it will yield much larger returns than could be expected from its spontaneous produce.

982. — 6. Soil continuedly ploughed yields its nourishment in much greater abundance, and with greater ease to plants growing upon its surface.

983. — 7. The facility with which the productive powers of well cultivated land are diminished depends on their being withdrawn into crops, and converted into products susceptible of conversion into air and water.

984. — 8. The decrease of fertility in carefully cultivated soil depends, in addition to all above circumstances, upon a diminution in the proportion of its imputable matter.

985. — 9. Cultivated land, when properly taken care of becomes gradually richer and richer, notwithstanding the increased quantity of produce annually removed from it.

986. — 10. If the same plant be cultivated for several years successively upon the same spot, the soil much more rapidly decreases in fertility than when a variety is kept up.

987. — 11. Theนอก cultivate soil contains several constituents which decrease in greater frequency in proportion to the greater care bestowed upon its cultivation, altogether independent of the portions removed by the crops.

988. — 12. More you pulverise a soil, the more alkali will be annually removed by the rain-water.

989. — 13. The Art of Culture, or the means necessary for keeping up the fertility of the soil, requires

990. — 1. Manure added in proportion to the weight of the crops removed.

992. — 3. Following, at least in some soils.

994. — 5. Manure must be added in proportion to the weight of crop removed. “It is believed that careful examination will prove that there exists between the crop and the active organic matter in the soil a proportion so constant and definite, that to keep up the fertility of the soil, we must keep up this
proportion; and if we do this by manure, of course it follows that there is a certain fixed proportion between the manure and the crop. Calculation will show us that at first sight the gross weight of the crops of a rotation is considerably above that of the manure applied, still, in reality, the amount of the various elementary matters is much nearer an equality, in fact so nearly so as to be sufficient to satisfy all, that there exists a certain proportion between the weight of the elements of the crop and that of the constituents of the manure.

8304. A rotation of crops is required, not merely because it tends greatly to lessen the expense of cultivation, but because the more azote a plant contains, the less frequently can it be cultivated upon the same spot in uninterrupted succession. "The precise chemical principles upon which a rotation depends are somewhat obscure."

8305. A narked summer follow only becomes necessary when soil cannot be cleaned and brought to a sufficiently fine tilth between harvest and the following seed time, without interffering with other operations.

8306. IV. The Economy of Husbandry, or the particulars regarding each individual crop, which are necessary in order to a profitable culture. In the following general facts in vegetable physiology will assist us in understanding this part of the subject.

8307. - 1. All plants in a highly artificial state require a larger supply of nourishment during the first period of their growth than is supplied by the seed alone; and hence the necessity of a rich soil, or of a supply of nutrient manure.

8308. - 2. Plants which have more than one method of propagating themselves should be limited to the method which is most suitable. The potato should not be allowed to produce seed, because it is most conveniently propagated by the tubers.

8309. - 3. Plants lay up a store of nourishment for the next year, either in the wood or roots, or in leaves and perennial, or in the seeds as annuals.

8310. - 4. The starch of plants is almost contained in cells, formed of a substance containing azote; and consequently there exists a fixed proportion between the quantity of azote composing the cells and the amount of starch contained in them; hence it follows, that to increase the quantity of starch in a plant, you must increase its supply of azote, although starch itself contains no trace of this element.

8311. In all parts of a plant, there is a fixed proportion between the constituent elements into its composition, so that an addition to one of them is necessarily followed by a relative addition to them all.

8312. If, for example, a plant possesses one part containing 2 grs. of azote, combined with 18 grs. of other elementary matters, in the proportion of 48 grs. of carbon, 20 ft., and 1 lb. of straw; if, by any means, the development of the more highly azotised portion, viz. the 2 to 18, we shall produce a proportionate increase in the other; so that, by preventing the formation of 20 grs. of the highly azotised portion, we obtain 56 grs. of that which contains proportionally less azote."

8313. "These facts will assist us in the following explanations regarding individual crops."

8314. The potato. "The potato differs essentially from the turnip, in that the portion used is a perfectly developed part, that is to say, a part which is perfect in itself; for instance, the bulb of the turnip is merely a deposit of nourishment for the use of the plant during the ensuing spring, and if removed from the plant, would not be of much use to the individual; whereas the tuber of the potato is a perfect individual as any seed, for it contains within itself all that is requisite for the propagation of the species. On this account, therefore, the potato may be considered as perfectly developed when the tuber is ripe; whereas the turnip is in a certain way to be considered as perfecting itself, while it is in its own most perfect state, when the seed is formed. Now, the importance of this distinction will be seen, when we remember that all plants deteriorate the soil most during the latter periods of their growth, and hence it follows that, *catērēs parenis*, the potato is a more exhausting crop than the turnip. The potato, like the turnip, contains much water, but the potato is more azotised than the turnip, but the portion containing the greatest quantity of azote is not developed until during the later periods of the growth of the plant. It possesses two ways of propagating its species, viz. by seeds and tubers, and never presents the development of the one, in lieu of the other, and that portion is regulated by the quantity of azote. The success of the potato depends mainly upon a due balance between the quantity of nourishment afforded respectively by the soil and the air, because the tuber consists of a large deposit of starch in cells, composed of an azoted organ and matter. Now, as the matter of the tuber is derived chiefly from the air, it follows, that if one or other of these supplies be in excess, a due proportion will not exist between the two ingredients of the tuber. Thus, if the soil be very rich in azotised matter, so many plants are produced that the leaves cannot eliminate starch sufficient to supply all of that azotised matter of which the plant is capable, and so it follows that the crop is not only deficient in azote, but any beams. With regard to the order of development of these parts, the cells are first produced with starch, and the potato consequently becomes 'mealy.' With regard to the order of development of these parts, the cells are first produced with starch, and the potato consequently becomes 'mealy.' With regard to the order of development of these parts, the cells are first produced with starch, and the potato consequently becomes 'mealy.' With regard to the order of development of these parts, the cells are first produced with starch, and the potato consequently becomes 'mealy.' With regard to the order of development of these parts, the cells are first produced with starch, and the potato consequently becomes 'mealy.'
production of starch, and the potato remains either waxy, or, what is worse, soft and watery. Now, a review of these facts would lead to the following suggestions regarding the culture of this plant:—

soil must be an enriched one; the plant must be thoroughly developed, the soil must be in a condition to yield azote abundantly, even during the latter period of the growth of the plant; hence, small quantities of active manure will not succeed nearly so well with this plant as with the turnip.

8105. 2d. "The manure need not be so well prepared, as the greatest supply of azote is not required until some time after the plant has risen above ground; but it must not be too fresh, for fear of retarding the development of the leaves, nor too hot, for fear of injuring injuriously on the root or tuber.

8106. 3d. "We must not give this crop too rich a manure, for fear of making a greater demand upon the atmosphere than it is capable of answering."

8107. 4th. "The plants should be placed far apart, so as to permit of the free increase of the leaves."

8106. 5th. "As the potato has a spreading root, and the tubers are developed upon the upper surface of the fibres which run more horizontally, it is very injudicious to earth up the plants, as this of necessity renders the roots more considerable loss.

8106. 6th. "To obtain the largest number of tubers, the flowers should be pinched off to prevent the formation of seed, while every thing should be done to protect the leaves from injury."

8110. 7th. "The soil for the potato should be loose, although this plant will grow in a much greater variety of soil than the turnip. This also depends upon the tubers being a completely developed portion, destined for the production of a separate individual; whereas, the bulble of the turnip is for the purpose of supplying the plant during the most important period of its growth; viz., during the development of the seed, with abundance of moisture and nourishment, when growing in a soil which cannot naturally retain supplies of both. Hence, it is impossible to grow turnips in a soil that is not rich at all, or else the bulb is very imperfectly developed, for in this case the soil can supply all that is required, without the assistance of this artificial reservoir."

8111. "Horse, oats, and barley. "All of the cereals agree in so many respects, that it will be advantageous to consider them together."

8112. 1st. "As they are cultivated for their seed, they are perfectly developed before harvest, and, therefore, exhaust the soil to a much greater extent than green crops; yet, from their system of growth, it is very much less probable that the plants before considered, they are much more dependent upon the soil even for those elements which larger leaved plants obtain from the air.

8114. 3d. "As the seed is, in all instances, the most highly azotised portion, and as it is the last part developed, that plants require more a general richness of the soil than a supply of newly added manure. On this account, it is with propriety, therefore, that they are seldom made to follow close after the application of manure, but are either preceded by a green crop, or are sown after summer fallow."

"These crops differ among themselves chiefly as regards soil and climate; wheat requiring clay, barley a lighter soil, and oats succeeding pretty equally on all good soils, of whatever texture they may be. The richness of the climate and the richness of the soil determines the climate, and the richest soil, then barley, and then oats. It is not easy to explain this satisfactorily, for although we can produce many circumstances which appear to explain the differences in question, more careful examination will prove that they can truly be considered in the light of probabilities, and by no means as certainly ascertained facts. For example, if we examine the ashes of these three plants, we find that their quantities amount proportionally to three, two, and one, wheat containing the most, and oats the least; and if we examine still further, we shall find that clayey soil is more capable of yielding the ingred- ients of ashes than land of a lighter texture. This renders it probable that one of the causes of wheat requiring clay, depends upon the necessity of a larger supply of these earthy particles; but accurate calculation also proves, that many plants which grow best on sand remove from it a greater quantity of the earthy substances which would be required to supply the heaviest crops of wheat from it, and cannot, therefore, be considered as proved, that the cause of wheat preferring clayey soil, depends upon the greater quantity of earthy matter required for its perfect development, although we may venture to advance as a probability, that it depends upon an increased facility of obtaining this supply. Again, these three crops require a considerable supply of air of a certain period before the appearance of flowers, the proportion being, wheat 2½, barley 1½, oats 1¼; so that here again, since we know that decomposition proceeds more slowly in clay, and the azote of the manure is hence not so quickly given off, we might well argue that clay is better fitted for the analysis of Chemical and mineral crops, and that the whole crops peculiarly suited to sandy soils contain a much larger absolute quantity of azote, although it must be admitted that the relative proportion is much less. Our conclusion here also, must therefore be, that the cause of wheat thriving best upon clay, depends probably upon its receiving azote in a greater degree of concentration."

8115. "Beans, peas, and other leguminous plants. "Very little can be said regarding these in the present state of our knowledge, as but little particular attention has hitherto been paid to them by the scientific inquirer; and there are so many peculiarities exhibited by them, that it would be very imprudent to risk an opinion upon so meagre a collection of facts. Beyond all doubt these are the most hardy crops we cultivate, as they are so very much influenced by the weather. Clover, for example, is a plant the success of which we can scarcely in any instance predict, as, no matter what the state of the soil may be, a few days of unfavourable weather may destroy at once all prospect of success. We may, however, notice one fact in this place, although we shall not attempt its explanation, viz., that the nitrates of potash and soda, two very favourable manures, appear to exert an almost magic influence over clover in rendering it more fruitful and luxuriant."

These observations complete Dr. Madden's review of the facts in agriculture, which are already explained by science; he regards them as showing that considerable advances have of late been made, and he hopes that the farmer and the philosopher may forward hand in hand in the field of agricultural improvement. He subjoins the following tables:

Analysis has proved the existence of more or less potass in all clays, as also in marls. From this table it would appear that by far the best soil would be that originating from the disintegration of felspar; and we think that observation will often prove this to be the case.

---

### BOOK II.

THE ANIMAL KINGDOM WITH REFERENCE TO AGRICULTURE. (p. 281.)

8116. — 1836. Animals, according to Liebig, are subject to the action of two powers which are constantly at work: vitality, which is the cause of life; and chemical affinity, which is the cause of death. The object of vitality is to sustain and increase the mass of the body in which it resides; the object of the chemical forces is to destroy and waste that body. Vitality resides in every part of the fortress which has to defend; the chemical forces are encamped in the atmosphere which everywhere surrounds it. In fact, the chemical power is the gas oxygen, one of the principal constituents of common air; and its affinity for the elements of organic matter is so great, that it constantly endeavours to destroy it. The whole life of an animal consists in a conflict of these rival powers; in the endeavour of vitality to sustain and increase; in that of chemical affinity to waste and destroy. In health, vitality possesses the ascendency, and modifies the destructive efforts of the chemical powers. Disease, on the other hand, is a temporary conquest of the chemical over the vital forces; while death is the victory of the former, and annihilation of the latter. (Journ. R. A. S. E., vol. iv. p. 221.)

8117. — 1863. The food of all animals, and particularly of those employed in agriculture, Liebig has shown to consist of two elementary substances: gluten or albumen, composed of carbon, hydrogen, nitrogen, and oxygen, which constitute the nutriment of the body; and starch, sugar, gum, and other substances containing carbon, hydrogen, and oxygen, but from which the element nitrogen is absent. It is only the substances containing nitrogen, or which in other words are azotised, which produce flesh, while the other elements are for the production of heat by the combustion of carbon in consequence of its union with oxygen. The heat generated in this combustion in the body of an animal, is exactly equivalent to that produced by burning the same amount of carbon in a fire or a candle. As the heat
of an animal body is the same in all regions, it follows that more carbonaceous food is required to keep up those rates in the regions of the body in which large movements or the maintenance of a high temperature are necessary. Thus the great importance of protecting animals from a greater degree of cold than is natural to them in every stage of their growth, and for obvious reasons it is equally important to protect them from extreme heat. This subject has been beautifully illustrated by Lellig, who says, "We have certain..." and we be able to reduce the temperature of their bodies. The first of these substances would only suffice to keep up the equilibrium between the temperature of the external air and that of our bodies." (Chemistry as applied to Physiology, &c.) The only use of clothes, says Dr. Playfair, is to economise the food by retarding heat. (Rationale of Dress. London: R. Ackermann, 1843, pp. 221.) The animal body is a furnace which must be kept up to a certain heat in all climates. This furnace must, therefore, be supplied with more or less fuel according to the temperature of the external air. If, then, in winter, we wish to keep the vital activity of the animal at the same degree of heat of their bodies. We may do it in two ways. We may either add more fuel (food to the furnace, or we may protect their bodies from the cold. Warmth is an equivalent for food, and as a proof, Dr. Playfair cites the following experiment, which was performed by the Earl of Duncannon. He kept two pens, each of which was 22 ft. in length by 10 ft. in breadth, and possessed a covered shed attached to it of 12 ft. in length by 10 ft. in breadth. They were kept in these from the 10th of October to the 10th of March. Each sheep consumed on an average 20 lbs. of Swedes daily. Another hundred were fed in pens of similar size, but were kept during the same time, and their daily consumption of Swedes amounted to 25 lbs. each. Here the circumstances were precisely similar with respect to exercise, the only difference being that the first hundred sheep had shelter into which they might retire, and thus be partially protected from the cold. This partial protection was equivalent to a certain amount of food, and consequently we find that the sheep enjoying this protection consumed one-fifth less food than those sheep which were left entirely exposed to the cold. In the last case the consumption of the additional food amounted to the necessity of the animal in order to keep up its normal temperature. This was proved from the circumstance, that those sheep which enjoyed the protection had increased 3 lbs. each more than those left unprotected, although the latter had consumed one-fifth more food. (Journ. A. S. E. 1843.) The heat stored in the dense bees is for the purpose of preventing the loss of heat from their bodies during the winter. Now it has been found that when two hives of bees are placed in one hive during winter, they actually consume less honey than each hive would have done separately.

8117 a. The assimilative power of the green parts of plants is much in proportion to the amount by which they can act. In summer, when the temperature of the air approaches more nearly to that of the body, the heat generated by the combustion of this food is more than is sufficient to retain the normal temperature of the system. Hence it is that we find oxen so much incommoded by hot weather, and the same is the case with all unsheltered warm-blooded animals. The hot sun heats the surface of the earth, and by this means causes a shower of rain. The cold water serves to carry off the redundant heat, and, consequently, matter, from the body; for heat is produced by the combustion of matter. This practice, therefore, has been possessed of a great advantage of a shield, which, by excluding the heat of the sun, is like a thermometer to exclude the heat, as in winter to retain it. "The air in summer being so much expanded by heat, much less air is taken into the system in an equal number of respirations than in winter; consequently less oxygen is consumed. But oxygen is the principal agent, and the cause of the death of waste; it has lost its chemical action, and is a cause of life, opposed to the chemical action of its reverse of what it is in winter. In cold weather, the vital force (cause of supply) is reduced in energy, whilst that of the chemical force is augmented; but in summer the vital functions are elevated and the chemical powers depressed. At this time the animal, having now a direct antagonism to its action, exerts all its powers in increasing the mass of the organs in which it resides; it therefore converts into blood all the parts of the food which the animal, except those which supply the small amount of waste. All the excess of blood is converted into flesh (i.e. muscular tissue and cells). Then, the excess of blood is converted into fat. The other substances, starch, sugar, and gum, are converted into fat, and deposited as adipose tissue. The cause of the deposition of fat is this: that sufficient oxygen does not enter the system to consume the food, or to convert it into carbonic acid and water; it therefore, is converted into fat. It is therefore, only one of the mass of the body is increased. For fat is a part of the organism; it is a chemical compound arising from an unnatural state. The fatting of cattle is similar to the growing of corn plants, or to agriculture generally. The object of agriculture is to produce an abnormal increase of some particular part of a plant. The phenomena of fatting are the same means, acting upon the same organs. The fattenin of cattle is similar. Our object is to produce an unnatural increase of some particular parts of the body; and to do this we must put the cattle in an unnatural state. (Journ. A. S. E. Vol. iv. p. 224.)

8117 b. The conditions to which the cattle, are food destitute of nitrogen, warmth, want of exercise, and in some cases darkness. Motion diminishes the tendency of an animal to fatten, by increasing the number of its respirations, and therefore by giving to the system an increased supply of oxygen gas, which consumes the tallow. Hence our practice of stalling feeding cattle. But this is illusory; that every manifestation of force, is the result of a transformation of the structure or of its substance; that every conception, every mental affection, is followed by changes in the chemical nature of the secreted fluids; that every thought, every sensation, is accompanied by a change in the composition of the substance of the brain. There are two antagonistic powers, vitality and chemical affinity. In the state of health, vitality retains the ascendency, and subdues the chemical powers; but this subjection is the result of much effort on the part of vitality, for the strength which is nearly equal, even under those circumstances, and is the single point in the fortress of the body, that moment the chemical forces begin the work of demolition on the unprotected part. Thus, vitality be called upon by the superior power, volition, to execute some purpose of its will,— to move the arm for example,— the vitality results in the action by which the motion is exerted. In motion, all its powers were exerted in preventing the encroachment of the chemical forces (i.e. of the oxygen of the air). But when it is employed in effecting a vital movement, such as that of the arm, it is to prevent being exerted in this antagonist attack of its antagonist, that are the powers upon the muscles, which obey the will, destroys part of their substance, and occasions its separation from the tissues. Poultry-feeders confine their poultry when it is necessary to fatten them quickly. The cruel practice of nailing the birds to the ground is opposed to the growth of fat. The want of exercise prevents the expenditure of a particle of the food by the motion of the animal. The greatest part of the food consumed by an animal thus deprived of the means of motion goes to the production of fat. When pigs are put up to be fattened, they are removed from the yard, in order to prevent any expenditure of the fat. When sheep are fed in the production of motion, the pig rapidly increases in size. Sheep fed in sheds consume from one-fifth to one-half less food, and increase one-third more in weight, than those fed in the open fields. The cause of these results is two-fold:—first, the sheep in the sheds are subjected to less motion, and therefore exhaust less food in its production, than those in the field; and, secondly, the sheep are kept warm in the sheds, and therefore expend less food for the support of animal heat than those
exposed to a cold atmosphere in the open fields. It is well known that the more bodily labour to which a man is subjected the more food must be received to supply the tissues wasted in that labour. In the late distress in Lancashire, the poor sufferers, who often were unable to obtain sustenance for themselves and families, discovered, through the forced necessity, both the theories which we have endeavoured to expound, viz. that warmth is an equivalent for food, and that motion is always accompanied by change of matter. We are informed by the daily press that whole families remained in bed for days together, covered with as many clothes as their small stock could furnish. In this state the animal heat was artificially reined in motion; consequently, a small amount of food was sufficient to support the vital principle."

8119. The importance of knowing how much water each kind of food contains, has been forcibly pointed out by Dr. Playfair, who has furnished the following table:

Thus, in giving a pig 100 lbs. of potatoes, we actually give it only 28 lbs. because 72 per cent. of this food consists of water.

8120. The comparative values of different kinds of food, as far as the production of flesh or muscular fibre is concerned, is not less important; because, as we have before seen, those kinds of food which do not contain nitrogen are only producible by fat or heat. The following table is given by Dr. Playfair:

In a cold day animals ought to be furnished with food containing a considerable amount of unazotised ingredients, in order to protect them from the effects of the cold. Potatoes are of great use in keeping up the heat of the body, and in forming tallow; but are in the highest degree unprofitable for forming flesh. It is true that potatoes would be required to form the same quantity of flesh that 100 lbs. of beans would do; whilst little more than 200 lbs. would suffice to form the same quantity of tallow; hence the great advantage of mixing food, so as to supply in smaller bulk those constituents of which one kind of food is deficient. Sheep fed on oil-cake increase in weight faster than on any other kind of food, but they feel quite soft, and when fat handle like a bag of oil. This is because they receive food which contains very little albumen to form flesh, so that tallow is the only product. But if with the oil-cake they receive oats or barley, they are firm to the touch, and possess plenty of good flesh, and the fat is equally distributed amongst the muscular fibre. The reason here also is obvious; for both oats and barley contain much albumen (or, chemically, gluten). In an experiment made by Mr. Morton at Lord Ducie's farm, twenty-eight pigs, put up in pens of seven each, and fed on an average of 15 lbs. of meat per pig and 4 lbs. of barley meal each, gained 15 lbs. weekly. In this quantity, the pigs actually consumed nearly equal quantities of the two kinds of food, or exactly 30 lbs. of dry potatos, and 23 lbs. of dry barley-meal weekly. The increase in weight being 16 lbs. for each pig, 57 lbs. of the food is lost in support the respiration, and the necessary muscular movements, even without taking into calculation the water contained in the flesh of the animal, which amounts to 75 per cent. If these animals had been deprived of muscular movement, by being placed in narrow warm cribs, it is reasonable to suppose that less food would have been lost, because less would have been consumed in the production of force, and in sustaining the animal heat. The barley-meal contains the constituents for furnishing firm flesh, as well as for producing tallow, or supporting respiration. The economy of using potatoes, consisted in supporting their respiration of the animals at less expense than barley. The 10 lbs. of potatoes used in this experiment for this purpose, and for the production of tallow, contains 26 lbs. of unazotised matter. In order to replace this, 33 lbs. of barley-meal would be requisite. It does not invalidate the conclusion, that 33 lbs. of barley-meal would produce a greater return than 106 lbs. of potatoes, because the former contains much more albumen and less water than the latter."

8121. The equivalent values of different kinds of food, if they could be correctly ascertained, would be of great value to the farmer, and the following table, translated from the French by Mr. Rham, may be considered as an approximation as can be obtained in the present state of our knowledge. On this table Dr. Playfair observes that an animal in a hot day will require much less food than in a cold day; that equivalence of food may be correct as far as the same animal is concerned, but may be of little value as regards other animals, because the size of the lungs of an animal occasions a great difference in the amount of food consumed.

4 0 3
S123. The form in which food is given to cattle is far from being a matter of indifference. If the food be in the form of hay, it is often difficult to attain, or difficult to retain, much of the nourishment obtained, much of the food being lost in the production of force necessary to adapt it to the organs of digestion. The cutting of hay and straw to cattle is unwittingly done with a view to prevent any unnecessary expenditure of force. Less mastication is requisite, and consequently less labor of the digestive system is required. The food for cattle in the system of Liebig, is to form a receptacle in which means is mixed with the food, and carried to the stomach. The use of mastication, then, is not only to comminute the food, but also to mix it with air or saliva. We find that a larger size of chaff is necessary in the case of the small herbaceous plants than is needed for the larger plants. In the former, than in the latter, than in the great object of mastication, we find that a larger size of chaff is necessary, because they consist nearly 90 per cent. of water, which becomes soon separated. Thus it is that cattle fed upon chaff voluntarily take 2 or 3 lbs. of straw daily, or as much as will serve to give the necessary bulk to the food. Ingestion is requisite in order to keep an ox in health. A little straw or hay is accordingly necessary to enable it to chew the cud. We know a case in which barley-meal and boiled potatoes were given to cows without hay or straw. Constipation resulted, and the cattle nearly perished from the ignorance of the feeders. From these considerations, we are induced to consider that a greater return will be made by feeding them not too much, than by feeding them with a small amount of chaff. The task is to the cow, the fact, that the sheep expend less force in chewing, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced. The task is to the cow, the fact, that the sheep expend less force in eating, is reduced.
it becomes enfeebled; and as vitality is the cause of increase in the body, any diminution of its power is highly prejudicial to growth. The amount of exercise must of course vary with the age of the animal.

18. That warmth is equivalent to food in feeding animals, has been already shown. Mr. Morton found that sheep will consume more turnips in the cold wet days of winter, than when the weather is dry and warm, and in frosty weather, more turnips than dry weather; these are still more so in dry summers, than the protection of a shed has saved one fourth of the whole food; and Mr. Chivers has shown (Journal R. A. S. E., vol. i. p. 407.) that where motion was at the same time prevented, the saving amount, as much as one half, and the deprivation of food, physiologists believe to be one of the great advantages of stall feeding. "The true state of health of an adult animal is, that the supply of food to the body should be equal to, but should not exceed, the waste of matter expended in the production of motion. This state is exhibited in a healthy animal, which weigh the end of the year as much as at the beginning. This is not the state desired in a fattening animal. We wish a diseased condition, or the state in which the increase of the body is far greater than the waste. We can beat through an animal into this condition by removing or diminishing the causes of waste. (Journ. R. A. S. E., vol. iv. p. 243.)"

19. Should cattle be fed in stalls, or in small yards with sheds attached? Certainly the former would appear at first sight to be more probable, because less motion is permitted. But it is also possible, that with the least amount of treatment, the energy of the vitals is more in proportion to the tissues of the body, and that the energy of the vitals is more equal, to prevent a rapid increase of the body; while, the health being better in the latter case, and only a small amount of exercise permitted, the increased energy of the vital powers may more than compensate for the loss experienced by the action of the motion of the animal, and therefore more fitter for the butcher; while the cattle tied to stakes will, in all probability, be possessed of more tallow." (Journal R. A. S. E., vol. iv. p. 245.)

20. The feeding of cattle for dairy purposes, has occupied Liebig and Dr. Playfair, but it would require more space than we can afford, to entertain their views, and we must, therefore, refer to the original sources. The same remark will apply to Dr. Playfair's remarks on the diseases of cattle, and on the recognised signs of fattening, and of early maturity. The theory of fattening adopted by Liebig and Dr. Playfair is, or appears to be, in opposition to all opinion hitherto entertained on the subject, and their peculiar aptitude of any animal, or of a breed, to fatten, is distinct from a peculiar smallness and fineness of texture of the lungs. Although Liebig has not announced in his work the opinion, that smallness of lungs is an indication of a tendency to become fat. The ground is that it is the opposite view which our most eminent physiologists recommend. We have found country, I find that they also entertain the same view. Cline asserts quite the contrary, and agriculturists have generally acceded to his opinion. He says, "an animal with large lungs is capable of converting a given quantity of food into more nourishment, and therefore becomes fat. Dr. Youatt holds a similar opinion. Mr. Youatt and Mr. Cline give their animals by reference to the capacity of the chest. On the roundness and capacity of the chest," says Mr. Youatt, "depend the size and the power of the important organs which it contains the heart and the lungs; and in proportion to their size is the power of converting food into nourishment. (Journal R. A. S. E., vol. iv. p. 257.)"

Those who would wish to pursue this subject will have recourse to the original, the interest of which would be in a great measure destroyed by abridgment, and it is too long to quote. We can, however, in our next numbers, give a translation of Liebig, the most interesting and instructive part of his work, with discourses with reference to agriculture which have appeared in our time.

21. The nutrient afforded to animals by seeds, and roots depends on the rupture of the ultimate globules which constitute their substance. These globules are usually from the fifteen-thousandth to the four-thousandth part of an inch; those of wheat rarely exceed the two-thousandth part of an inch, and so on. From experiments made on these globules, by M. Bascul, the author of Chemic Organique, and M. Biot, of the French Academy of Sciences, who have celebrated for his researches in the polarization of light, the following conclusions have been drawn.

1. That the globules constituting meal, flour, and starch, whether contained in grain or roots, are incapable of appetizing by any animal (till they are broken) without the assistance of digestive organs.

2. That the mechanical method of breaking or grinding is more than partially efficient.

3. That the most efficient methods of breaking the globules is by heat, by fermentation, or by the chemical agency of acids or alkalis.

4. That the dextrine, which is the kernel, as it were, of each globule, is alone soluble, and therefore alone nutritive.

5. That the shells of the globules, when reduced to fragments by mechanism or heat, are insoluble, and therefore not nutritive.

6. That, though the fragments of these shells are not nutritive, they are indispensable to digestion, either from their dis-tending the stomach and bowels, or from some other cause not understood; it having been proved by experiment, that these carbonated nourishment, which consists of beef, or other animal flesh, cannot long sustain life without some mixture of coarser and less nutritive food.

7. That the economical preparation of all food containing globules of starchy consists in perfectly breaking the shells, and rendering the dextrine contained in them soluble and nutritive, while the fragments of the shells are at the same time rendered more bulky, so as the more readily to fill the stomach.

Quoted by (J. A. R., vol. vii. 496.)

22. Comparative advantages of feeding live stock on raw, or on prepared food. In 1839, the Highland Society of Scotland offered handsome premiums for reports on this subject. Five of their Reports are published in the Highland Society's Transactions, vol. x., by which it appears that no benefit whatever is gained by the practice in the case of cattle, but on the contrary, a less equal to the amount of fuel and the cost of labour. Swine, on the contrary, afford a greater return. These experiments were made in the following order of experiments.

On steamed food increased 173 lbs., being 67 lbs. more than double; while those on raw food increased only 115 lbs., being 7 lbs. more than double their first weight. Hence there can be no doubt that steamed food is more profitable for different species of cattle, and that raw food, especially raw potatoes, which when given alone are found insufficient for bringing a pig to fat state. (Transactions H. S. vol. x. p. 280.)

23. Progress of education in rearing and training brute animals. The effect of gentleness in teaching the human species has been long observed, (generalising on the subject) the same effect has been observed in the education of cavally horses. Gentle treatment is the principal object in the treatment of young animals in the stable, and in the education of the animal, the most that can be done is to render them docile; and the same gentle means are now used for that purpose which are used in the education of children. They are not only quiet and tractable, but are not taken up their feet, or the struggle of the animal, and to the study of arms; and in the course of four or five months afterwards, they are transferred to the riding-school to be trained. The gait of the animal, that preferred by our ancestors for teaching boys Latins and geographers, is now all fear and shyness out of them, but kindness and common sense have at last gained the ascendency, to the great delight of the organs of sensation in both boys and horses. (G. M. 1834, p. 313.)

...
833. Training calves and horses.—In Ellis’s Horse Training, reviewed in the Athenæum for April 2, 1842, it is shown that breathing into the nostrils of calves, horses, and various wild animals, renders them quite tame. The experiment has been tried in England with success; and Mr. Ellis is of opinion, that this is the secret of the celebrated Irish horse charmers, who pretended to whisper to the animal and place this little prayer under it, and it was probably breathed into its nostrils. The experiments made by Mr. Ellis are founded on the following passage in Mr. Clinton’s work, Indian Tribes and Customs of the Northern American Indians:—“I have often, in concurrence with a well-known custom of the country, held my hand over the eyes of the calf and breathed a few strong breaths into its nostrils: after which I have, with a little ceremony, robed it out into our stable. We had several miles in our road: on following the heels of my horse, the whole way, as closely and affectionately as its instinct would attach it to the company of its dam. This is one of the most extraordinary things that I have met with in the habits of this wild country; and although I have often heard of it, and felt unable exactly to believe it, I am now willing to bear testimony to the fact, from the numerous instances which I have witnessed since I came into the country. During the time that I resided at this post, in the spring of the year that we were on the way up the river, I assisted (in numerous hunts of the buffalo with the Fur Company’s men) in bringing in, in the above manner, several of these little prisoners, which sometimes follow for five or six miles close to our horses’ heels, and even into the Fur Company’s fort, and into the stables where our horses were led. In this way, before I left for the head waters of the Missouri, I think we had collected about a dozen or more of these wayward animals. We knew them to be kept from harm by the lasso, and a pair of hobble on his feet, and at length, to breathe in its nostrils, when it soon becomes docile and conquered; so that he has little more to do than to remove the hoople from his feet, and lead or ride it into camp.”

In confirmation of what has just been stated, we quote the following:—“The taming of horses,” says the Newbourn Advocate (a North Carolina newspaper), by breathing in their nostrils, seems to be gaining friends. Mr. David Clayton, of Tyrrel county, having seen an article in our paper stating that horses had been rendered gentle by breathing into their nostrils, determined to try it on a young mule belonging to him, who would suffer no person to handle him. Mr. Clayton fastened him in a stable, and, after considerable trouble, succeeded in breathing several times in his nostrils. Before he left the stable the mule became gentle, and would stand still and suffer himself to be rubbed, and would now allow Mr. Clayton to handle him. He declared Mr. Clayton ought to be paid for his experiment. “It is important,” he added, “to have our friends who have colts to break to try the experiment; if it does no good, it can certainly do no harm.” (G. M. 1842, pp. 328, and 571.) The subject of training horses in this way is said to be mentioned by M. Casaubon, in his Traité sur l’Enthousiasme, published in 1665; who refers to one Sullivan, a blacksmith at Cork, who practised the art. The same statement will be found in Stewart Rose’s translation of Partenopeo de Blois, and in a note in Burrow’s Bible in Spain.

We have introduced it in this Supplement in the hope that it may induce such experiments to be made as may set the matter at rest.

BOOK III.

THE MINERAL KINGDOM AND THE ATMOSPHERE WITH REFERENCE TO AGRICULTURE.

CHAP. I.—Earths and Soils. (p. 312.)

833.—2100. Humus or mould exists in all soils, and indeed is necessary to constitute soils as distinguished from earths, which consist solely of inorganic matter. It was formerly thought that humus was soluble in water, and in that state was taken up by the roots of plants; but Liebig has shown that it is insoluble in water; that if it were, it would soon be washed out of the soil by rains and melting snow; and that it only supplies food through the action of the oxygen of the atmosphere, with which it forms carbonic acid gas. The complete, or it may be said, the absolute insolubility in cold water of vegetable matter in progress of decay, (humus,) appears on closer consideration to be a most wise arrangement of nature. It is possessed of a degree of tenacity, or rather a smaller degree of fluidity than the substance called humic acid, it must be dissolved by rain water. Thus, the yearly irrigation of meadows, which lasts for several weeks, would remove a great part of it from the ground, and a heavy and continued rain would impoverish a soil. But it is soluble only when combined with oxygen; it can be taken up by water which in a dry condition may be perfectly insoluble; but when moistened with water, it converts the surrounding oxygen into carbonic acid. As soon as the action of the air ceases, that is, as soon as it is deprived of oxygen, the humus suffers no further change. Its decay proceeds only when plants grow in the soil containing it; for they absorb by their roots the carbonic acid as it is formed. The soil receives again from living plants the carbonaceous matter it thus loses, so that the proportion of humus in it does not decrease.” (Liebig’s Chemistry of Agriculture, art. 25, p. 11.)

833.—2112. Irrigation. Sir Humphry Davy was unable to satisfy himself as to the cause of the benefits derived from irrigation, ascribing it chiefly to the protection of the grass from early spring frosts; but if we admit, with Liebig, that inorganic salts are necessary to the well-being of plants, and promote an increased development of the part of them, we shall explain the beneficial effects of irrigation very easily. The clearest spring water holds in solution carbonate, sulphate, and chloride of lime, with silicate and other salts of potash and soda. “Reeds and equisetaceae thrive in ditches and streamlets, because a large portion of silicate of potash enters into their composition; and, by the frequent change of the water, dissolved silica is largely supplied. The meadow grasses likewise require silicate of potassa, and they are furnished with it by the water which flows over them while under irrigation. The carbon also, and the carbonaceous excrement of plants contained in the soil, require abundance of oxygen to promote their decay and conversion into carbonic acid. Now the water of rivers and streams holds oxygen in solution, and if, during the process of irrigation, the water be frequently renewed, no matter how thin the sheet of it with which the meadow be covered, it will communicate large supplies of oxygen, and thus dispose of the matters contained in the inorganic matter of the soil. On the contrary, retards their conversion into carbonic acid by preventing the access of air, and hence arises the sterility of hogs and marshes. In order to convert them into luxuriant meadows, it is only necessary to renew the stagnant water by draining, and, where practicable, to irrigate the land by means of water rapidly renewed.” (Trimmer’s Chemistry for Farmers and Landowners, p. 199.)

834.—2117. Rotation of crops. The theory of the rotation of crops adopted by Liebig is thus ably given in an abridged form by Mr. Trimmer. Formerly the soil was supposed to contain a variety of substances, in which each was useful to some of the plants, and the atmosphere furnished a constant supply of each plant absorbed those substances which were suited to it, and rejected the rest. “Subsequent observations caused the following modification of this theory; viz., that plants absorb indiscriminately whatever they require to their solution, and that a state of saturation is produced, affecting them, and expelling as excrement that which is unsuited. Some experiments were made by Macacé Princeps, in which plants were made to vegetate in a weak solution of acetate of lead, and were sprinkled...
with nitrate of strontian. In each case they absorbed the substance thus presented to them, for it was detected by analysis in their structure, but they expelled it again. These experiments offered strong confirmation of the above views, and rendered a satisfactory explanation of the fact, that a plant like wheat, which contains much potash, will not nourish after another crop, and require a new one. This is accounted for by the fact that it thrives after clover, beans, peas, or other leguminous plants, which scarcely contain any alkalies; but they did not explain how land becomes fertilised by following, nor how leguminous plants cause an increase of carbonaceous matter in the soil. Other experiments, however, made by him have established the fact, that most if not all plants expel whatever their organs are unable to convert into woody fibre, starch, gluten, &c., and that these substances are of two kinds, inorganic matters derived from the water, which are incapable of assimilation; and organic compounds formed in the plants by the vital process. He found, for instance, that when leguminous plants were grown in water, it acquired a brown colour; that other plants of the same kind would not grow in this water, but that the plants of corn throwe in it and removed some of the colouring matter. He ascertained, too, that of the organic matters they are capable of assimilating, some are like gums, and others, as lime and gypsum, are regarded as poisonous, the latter as nutritious to succeeding crops. These organic matters, thus expelled, by the roots, and deposited in the soil, restore to it the carbon, which in the early stages of their growth is thrown off in a shape of carbonic acid gas. The rapid process to which these new plants are subjected, being deprived of nutritive matter, impels them to assume a new and rapid mode of nourishment. It is accelerated by the presence of lime, while argillaceous soils are those in which the longest time is required for its completion. The excrements of a given crop must be thoroughly decomposed before the land will produce another of the same species; and on those soils on which the longest intervals are required between crops of the same kind, it is found that the time cannot be shortened by the most powerful manures. Now calcareous soils are those on which peas, clover, &c., will bear to be repated at the shortest intervals, and argillaceous soils are those on which the longest periods are required between them. But though these excrements, undecomposed, either wholly or in part, are injurious to plants of the same species as those which expelled them, they are not so, nay, are even capable of affording nutriment, to those of other species; and therefore the introduction into cultivation of every new plant which can supply the place of another, such as clover or turnips, which will not bear frequent repetition, confers the farthest possible advantage in bringing him with the means of varying and extending his rotation.
various soils, in which last particular English science is sadly defective: for, Dr. Liebig observes, Davy has made several analyses of various fertile soils, and since his time numerous other analyses have been published, but they are all so superficial, and in most cases so inaccurate, that we possess no means of ascertaining the real chemical analyses of English soil. Our science ought certainly to be removed; and it is easy to see how varied a field of inquiry is opened by the new theory.'

(Journ. R. A. S. E., vol. iii. p. 214.)

5891. The practical application of manure. Mr. Pusey has given the following summary as the result of recent experience. On this most difficult subject in agriculture, manures, ‘it may be said that we have learnt a great deal in the last four years, but know nothing: for we have learnt many of the chemical principles on which manures act, but we do not know how to apply them.

For ammonia, the most important of all the farm-foods, is used in the application of manure. We are familiar with the common ammonium, which has been found to be the most powerful of all manures; the other, that it has experience in its favour, though a distant experience certainly, at the other side of the globe, in Peru,—still an experience of 20 years. It is, however, a principle that the root-crops, to be best for roots, must be raised on soil that has been turned over, and that the last year for turnips is the year before the manure was applied. It is also a fact that the manure should be applied to the land in the spring, and not at the beginning of the season. For manure, in any case, whether it is liquid or solid, will at least four or five times its weight of water, and the addition of water acts considerably on the action of the manure.

5891a. Rape-dust appears to be established chiefly among the farmers of Nottinghamshire, Yorkshire, and Lincolnshire. As it is one of the few hard-tillages which can be applied to clay, and as some of our soil heays are very clayey, it may be added to the list of useful manures. In the essay of the Wetherby Agricultural Society, by Mr. John Hannam, the best mode of using it is drilling with autumn-sown wheat at the rate of 4 or 5 cwt. to the acre, the price being about 7s. per cwt. Mr. Hannam states that the use of rape-dust has increased in the counties of Kent, Sussex, Oxford, and Berkshire. The price is about 6s. per ton. They answer extremely well for hops and wheat. They are usually cut up by chopper into shreds, and applied by the hand at the rate of 6 or 7 cwt. to the acre. Six or 7 cwt. is considered a fair dressing for wheat upon light land; on heavy land rags are not used at all.

5891b. Nitrate of soda, from which so much was once expected, has given various and contrary results. There are the most unbounded proofs from numerous quarters of an enormous increase in the produce after its use; there are as unbounded instances of its utter failure: nor have we any clue to the mystery. A full statement of all the recorded experiments on nitrate of soda is contained in Professor Johnston's Chemistry and Geology applied to Agriculture, the most complete account of agricultural chemistry that we have seen. Mr. Pusey says, ‘we have never given Mr. Pusey's nitrate of soda at the following; and having tried it largely at that time on four different farms, nowhere with success, he has given it up. Still there is evidently a principle of fertility in it, which will some day be found out, and some farmers continue to use it; but in several cases it has produced mildew in wheat and barley, causing the crop beyond the strength of the land.' By the side of the nitrate Mr. Pusey tried on several fields the sulphate of ammonia, extracted from gas-water, for the first time. It acted precisely as the nitrate of soda, darkening the colour of the plant, and lengthening the straw and ear even more, though the nitrate, but certainly did not pay. Again we have the principle, and we must learn to combine it.
manure. Whether it could be adopted elsewhere, with the same advantages, is a very interesting question, as is the mode of its operation. Dr. D. Day's theory, that it dissolves vegetable matter, is given up; in fact, it dissolves only a certain variety of vegetable fibre. Some persons think that it should be applied hot to the surface of the soil, and let the operation follow its own course, and leave it to its own view upon chemical principles, but at present it seems to be well to do so still. Dr. Liebig has recently discovered that the root of a grass plant is not decomposing clay, but producing potash and soda, which are much more injurious to the surface than to mix lime. Now, if this be the mode in which lime acts, there could not be a more practical and the old practice would agree with the true theory, as shown by some of the experiments. All of these must we guard against premature inferences from any single case. Of the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and they may be given to agriculture.

114. A great desire to improve in agriculture hitherto has been to keep up and increase the fertility of the soil by returning to it, in the form of manure, more food for plants than it can receive from the soil or air. As to the degree of success, this is not fully known. Whether it could be adopted, or the mode of its operation, Sir H. Dr. Liebig has recently discovered that before it is applied to the surface of the soil, it would be well to do so still, Dr. Liebig has recently discovered that the root of a grass plant is not decomposing clay, but producing potash and soda, which are much more injurious to the surface than to mix lime. Now, if this be the mode in which lime acts, there could not be a more practical and the old practice would agree with the true theory, as shown by some of the experiments. All of these must we guard against premature inferences from any single case. Of the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and they may be given to agriculture.

115. A great desire to improve in agriculture hitherto has been to keep up and increase the fertility of the soil by returning to it, in the form of manure, more food for plants than it can receive from the soil or air. As to the degree of success, this is not fully known. Whether it could be adopted, or the mode of its operation, Sir H. Dr. Liebig has recently discovered that before it is applied to the surface of the soil, it would be well to do so still, Dr. Liebig has recently discovered that the root of a grass plant is not decomposing clay, but producing potash and soda, which are much more injurious to the surface than to mix lime. Now, if this be the mode in which lime acts, there could not be a more practical and the old practice would agree with the true theory, as shown by some of the experiments. All of these must we guard against premature inferences from any single case. Of the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and they may be given to agriculture.

116. A great desire to improve in agriculture hitherto has been to keep up and increase the fertility of the soil by returning to it, in the form of manure, more food for plants than it can receive from the soil or air. As to the degree of success, this is not fully known. Whether it could be adopted, or the mode of its operation, Sir H. Dr. Liebig has recently discovered that before it is applied to the surface of the soil, it would be well to do so still, Dr. Liebig has recently discovered that the root of a grass plant is not decomposing clay, but producing potash and soda, which are much more injurious to the surface than to mix lime. Of the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and they may be given to agriculture.

119. A great desire to improve in agriculture hitherto has been to keep up and increase the fertility of the soil by returning to it, in the form of manure, more food for plants than it can receive from the soil or air. As to the degree of success, this is not fully known. Whether it could be adopted, or the mode of its operation, Sir H. Dr. Liebig has recently discovered that before it is applied to the surface of the soil, it would be well to do so still, Dr. Liebig has recently discovered that the root of a grass plant is not decomposing clay, but producing potash and soda, which are much more injurious to the surface than to mix lime. Now, if this be the mode in which lime acts, there could not be a more practical and the old practice would agree with the true theory, as shown by some of the experiments. All of these must we guard against premature inferences from any single case. Of the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and the following extracts are taken, Mr. Oliver has long been known for his practice of opinion, and they may be given to agriculture.
Mr. Fleming, of Barochan, obtained also nearly equally favourable results from the application of nitrate of soda and sulphate of soda to clover and rye-grass hay; though he seems to have applied the latter in only half the quantity suggested by Professor Johnston: 160 lbs. nitrate of soda gave 1 ton of additional hay per imperial acre, and the same quantity of sulphate of soda about 8 cwt. only.

Mr. Fleming gives also a tabular view of results on a field of wheat with a considerable variety of manures, on which Mr. Johnston makes the following remarks:—"This table presents us with two remarkable results; that obtained by the use of common salt, and that from a mixture of soda and rape-dust. Thus, exclusive of the straw.

"Nitrate of soda alone gave 152 lbs. of wheat for 31s., or 12s. 2d. per bushel.

"Nitrate with rape-dust gave 400 lbs. of wheat for 43s. 6d., or 6s. 6d. per bushel.

"Common salt gave 472 lbs. of wheat for 3s. 6d., or 6d. per bushel.

The increased produce by the use of common salt is by far the most valuable result to Mr. Fleming, in an economical point of view, and plainly indicates the kind of application he can most profitably make to his wheat crops, at least on land similar to the above, and in the district where he resides.

"Neither the nitrate of soda, nor the mixture of this salt with rape-dust, gave such an increase as to repay their own cost, unless when corn is very high. It is interesting, however, to observe, that the mixture with rape-dust gave so large an increase, though the value of this particular experiment is lessened by the absence of any trial with rape-dust alone, by which the effect of each of the ingredients ought to be judged of. I have reckoned the rape-dust at 7l. a ton, so that 5 cwt. would cost 28s.; and we have therefore, in top-dressing of this substance alone, in a somewhat larger quantity, gives a remunerating return in many of our wheat lands."

Mr. Fleming's experiments on oats, potatoes, &c. afford equally interesting results, and are deserving of the attention of those who feel an interest in agriculture, but I shall confine myself at present to that made on early potatoes in 1841, which cannot be more clearly or shortly stated than in Mr. Fleming's own words.

"All were dug in the usual manner with farm-yard manure, at the rate of about 30 cubic yards per acre. The potatoes were all planted on the 26th of March, on the same black soil. The several dressings were applied on the 20th of May, and the potatoes were all lifted on the 28th of September.

Note.—The peck is 35 lbs. weight, and 16 make a bolt, or 5 cwt.

This break of ground consists of a piece of poor clay, mixed with moss, about 9 inches deep; subsoil a very stiff blue till. The dung was old from the farm-yard, about the ordinary quantity (30 cubic yards per acre), spread upon the land dug in. The potatoes were drilled in with the hoe; as the ground was wet, the plants came up but weak. The nitrate of soda was given before the top-dressings, and had remarkably quick effect, as it showed the third night after being sown. The sulphate of soda does not occasion the dark green colour which is seen upon the potato dressing of the nitrate; but it gives the plants the smallest dose of its beneficial effects, although not in so great a degree as the nitrate. The mixture, which is composed of two-thirds of soda and one-third of the nitrate, has a wonderful effect in strengthening the growth (which it keeps longer than with nitrate alone), and the mixture has the same effect in producing the dark green colour as the nitrate alone."

In remarking on this with me, Mr. Fleming's gardener, observes: " Those who are the most sceptical in regard to the benefits to be derived from agricultural experiments, when well conducted, will scarcely question the importance of this result; the most backward in making experiments will be anxious to repeat this upon his own potatoes. The cost of the mixture to be applied, in the quantity used by Mr. Fleming, is as follows: —

£ s. d.

Sulphate of soda, 75 lbs. dry, at 10s. per cwt., or 150 lbs. in crystals, at 5s., - - - 0 6 9

Nitrate of soda, 75 lbs. at 22s., - - - 0 14 9

£11 6 0

The return for this 21s. 6d. was in each of the above cases upwards of 8 tons of potatoes."

Though the number of experiments made, and inferences which can be safely deduced from them, are far too numerous, and our dwelling confined, success, you may perhaps be enticed to think, that they are such as to hold out sufficient encouragement for further prosecuting the inquiry.

This, I apprehend, can only be successfully done by the united efforts of the practical and chemical agriculturists; the former by instituting and carefully conducting experiments on a systematic plan; the latter by tracing the facts so obtained to the laws of nature on which they depend, and the progress which, in all probability, be in proportion to the number of practical men who can be induced to engage in making experiments, and the results of experiments with experiments on a systematic plan; in all cases to analyse the soil to be experimentally worked on, and to ascertain by weight the kind and quantity of the material to be applied, as well as the quality and quality of the produce obtained from the application of each description of manure. This, however, is an inquiry which cannot be successfully prosecuted by a few individuals, and the results of such a variety of experiments by divers of soil, climate, situation, season, and a variety of other circumstances, combine to throw doubt on results so obtained, however carefully conducted. But this should not deter us from pursuing the inquiry, on the contrary, it is an additional reason for all who have it in their power, whether owner or occupier, contributing their share."

Mr. Oliver concludes: "Assuming, then, that the object in view is of sufficient importance to merit the attention of this Society, and that the few experiments which have already been instituted hold out sufficient encouragement for expecting a successful result, I trust I shall neither be considered pre-
Supplement. Science and Art of Agriculture.

1309

numinous nor over sanguine in expressing my hope that the Society will give the subject their best consideration, and afford such aid as seem to them best calculated to secure the co-operation of practical agriculturists, in instituting and reporting the results of experiments, carefully made on a trial plan, and succeeding in bringing that a wide, fertile, and unexplored field in agricultural improvement lies before us; and although it may be ventured an opinion as to the results which the combined effect of science and enlightened practice may accomplish, and less politely, be pressed, to rest satisfied with our present knowledge. Let practical men, therefore, establish facts by experiments, and draw conclusions, whether from the suggestions of their own mind or those of others; and let the duty of tracing these to the source of life and prosperity, be lightly discharged by men of science; and perhaps the progress may be more rapid, and the success greater, than it would be either wise or prudent to anticipate at present." (Trans. H. S., vol. xiv. p. 525.)

562. Experiments with Saline manures. Made on a farm in Essex, gave the following results, which may be depended on for those who have a field of wheat or barley, of about an acre each, 1416 lbs. 2 cwt. with 28 lbs. of sulphate of ammonia; corn, 1612 lbs. 3 cwt. With 140 lbs. of the same salt; corn, 1999 lbs. 4 cwt. With 112 lbs. of nitre, corn, 1805 lbs. 5 cwt. With 112 lbs. of nitre; corn, 1899 lbs. The increase in the straw was also considerably much as the use of the small proportion of sulphate of ammonia. The total increase in the four manured crops was, per cent. to the whole in which the grain was sown, 18-l2 per cent. The cost of the manure for the three last did not greatly differ, being 21s. 6d., 24s. 6d., 27s. 6d. The profit on the outlay was, with the small dose of sulphate of ammonia, 294 per cent; with the large dose, 292 per cent. The principal conclusions drawn by the author, are, that the increase of the nitrogen in the soil is very small, and what is counted for by the nitrogen of the manures, showing that these manures have a stimulating effect, or enabling a plant to draw additional nitrogenised food from the soil and atmosphere; the considerable superiority of sulphate of ammonia over the other salts, and the greater proportional effect of this than of a large dose of that salt. The sulphate of ammonia costs 17s. per cwt. It appears best to apply this salt in the proportion of about 1 cwt. per acre, at three different dressings, the first quantity when the crop, if wheat, is sown in the fall, or, if oats, at the end of the summer; the second quantity about a month afterwards; and the third quantity at the time of the formation of the seed. To meet the practical difficulty of distributing so small a quantity as one third of a cwt. over an acre, agriculture can make use of sulphate of soda, which is not volatile, like the carbonate, if acted upon by the sun. Fresh manure, like urine, contains ammonia, which it is important to preserve, but which is generally wasted by the common modes of managing manure. (G. C. 1842, p. 191.)

"Dr. Sprengel, after describing the various methods of employing liquid manure, uses these strong words: 'It is a duty for agriculturists to collect the water of manure, however, if he be compelled to do this, mixes no water with it, or who fails also to employ some neutralising substance con- bine with the ammonia, which is produced in so great a degree during the summer, — suffers a loss of manure which exceeds of the entire liquid manure of great power is the result. It has for many years been the custom in Switzerland to reserve stable urine, to wash the fresh manure, and to collect the fluid in reservoirs, where, after fermentation has been carried on, the urine is converted into a modification of ammonia by sulphate of iron (green vitriol), sulphate of lime (gypsum), or sulphuric acid (common vitriol). The fluid thus obtained, when employed for watering land, produces a strong vegetation, an effect that is ascribed to the sulphate of ammonia, which is not volatile, like the carbonate, if acted upon by the sun. Fresh manure, like urine, contains ammonia, which it is important to preserve, but which is generally wasted by the common modes of managing manure. (G. C. 1842, p. 51.)

814. To ascertain whether or not a liquid contains free ammonia. Take a spoonful of common turmeric and mix it with a little water; keep aside one-half of the greenish yellow paste thus formed, and mix the remainder with three or four times its bulk of the black pepper, and examine. If it contain any free ammonia, the liquid becomes immediately of a reddish brown colour; the deeper the colour depending on the quantity of free ammonia it contains; upon the addition of a few drops of any acid the former is neutralised, and the liquid becomes a hazy yellowish red colour. The value of any acid or other substance as a fixer of ammonia may be well tested in this manner; the liquid must be mixed with a little of the powdered root, which it will immediately redder. The other sample, required for any quantity of the manure, is known by observing how much of it must be added to bring back the original yellow colour of the turmeric. Turmeric root may be procured at almost any chemist's; if only the whole roots can be obtained, they are readily reduced to powder on a common grater, like ginger. (E. Solly in G. C. 1842, p. 808.)

815. Test for the presence of Ammonia. A strip of paper previously rubbed over with petals of the common mallow will be turned green, if the ammonia predominate in the liquor. The absence of the ammoniacal smell is a very certain proof of the saturation of the ammonia by the sulphuric acid, and the use of the wash water will tell. (G. C. 1842, p. 747.)

819. Nitrate of Soda. The effect of this manure in increasing the value of the hay crop, has been strikingly exemplified in numerous instances. Mr. Grey, of Dilston, dressed one portion of a field with nitrate of soda, and nitre of sulphate of ammonia, and kept a portion of the field without any dressing. This was done in May, at the expense of 34s. per acre for the nitrate of soda, and 2s. 4d. for the nitre and manganese, and when the hay was made the produce was found to be tons 88; 8 in the former case, 3 tons and 21 stone in the latter, and only 2 tons and 37 stone on the space which received no dressing. (Trans. H. S., vol. ii. p. 231.)

820. Natural silicate of potash for manure. Potash being drawn from the soil by every crop, requires constant renewal. The ordinary resources are, vegetable ashes of different kinds, such as wood, some kinds of leaves, turmeric, the straw. The potash thus gained by both of man and beast, is restored chiefly in the form of liquid excrement, which runs to waste in our towns, sewers, and common yard drainings. Liebig proposes to procure the silicate of potash from the ashes of burnt wood, but M. Proust, an eminent French chemist, suggests the idea of obtaining it from Dartmoor or other granite, by burning and mixing with lime. The details of the process will be found in the Brit. F. N., N. S., vol. vii. p. 102.

830. Effect of mixed manures. It is probable that one of the reasons why natural manures are so much more productive, is their effect of the manures of different kinds, so that if one does not take effect upon a crop, another may. Thus we see that farm-yard dung, guano, and composts, produce invariably a good effect; while nitrate of soda, sulphate of soda, and the other saline ingredients now so extensively employed, sometimes succeed, sometimes fail, and always succeed best when used in addition to the ordinary manures. Experiments show that plants are but little
Improved by simple substances when they can get nothing else, and that it is only when the soil in which they grow has been manured, and still retains a quantity of the organic matter so introduced, that the effects of manures become apparent. This is true not only of crops raised under greenhouse, but even of roses and other flowers, the effects of which experiments were made by Mr. Fleming, of Harrowden. On a soil which, without being recently manured, produced 61 tons of the red dragon potato, 50 bushels of wood-ashes (which may be regarded as a simple manure) were applied at the rate of 2 cwt. per ton of the quantity of natural guano, a very compound substance, added more than 71 tons, at the total cost of 6s. 10d. (reckoning guano at its present price). But when 25 bushels of wood-ashes were added to 4 cwt. of guano, the crop rose about 1 ton further, at the additional cost of 12s. 6d. So that, where wood-ashes were used alone, the small quantity used by them was more than doubled, while, those added with the guano furnished potatoes at the expense of only about 8s. a ton. To the guano and wood-ashes 20 bushels of charcoal were added, at a cost of 7s. 6d., and the effect was to add 1½ ton more to the crop; so that now the additional crop cost scarcely more than 4s. a ton. This may be stated a little differently in the following manner:—Where wood-ashes (a simple manure) were used alone, the potatoes, obtained beyond what the land would yield without any manure whatever, cost 11. 13s. 6d. per ton. But where wood-ashes were used in addition to more complicated manures, the crop was largely augmented, at an expense in manures, which, only to from 11. 13s. 6d. to 16s. 6d. per ton of the extra produce. These things seem to prove conclusively that the best way of using saline or simple manures for the potato-crop is to apply them in addition to common manure, and not on account to try to use them by themselves. (G. C. 1843, p. 227.)

The value of guano is the subject of much discussion, and is understood in two different ways. It is applied to both maize and potatoes when about 2 ft. high, at the rate of a small handful to three different stools of plants. Water must be let on within two or three days after the guano is applied. (Mark Lane Express, as quoted in G. C. 1843, p. 175.)

Cloacin and Fospin salts, recommended by Liebig as a powerful manure for potatoes. One ton of cloacin, or four tons of the best Fospin salts, will dress 50 acres, and 40 tons of the latter, 200 acres. The dressing is made at the rate of three quarters of a ton for each acre, and should be applied in the manure. Any saltpetre, or a substitute for it, will answer the same purpose, as the manure will have to be turned into the ground before it is saturated with the water. For potatoes, the dressing should be made in the manner prescribed for cloacin and Fospin salts. (G. C. 1843, p. 260.)

1854—2290. Cloacine may be disinfected by earth which is very rich in vegetable matter, and by mud from ponds. (G. C. 1843, p. 200.)

1855—2270. The treatment of stable dung by M. Schattenuhm, of Boixwiller in Alsace, is thus described by himself:—‘I have for many years been in the habit of treating stable-dung in a manner entirely different from that which is commonly practiced. At Boixwiller I have had for several years the control of the stable, of which the yard is occupied by a single herd of horses and a straw bed about the size of my own. There I have formed a trench for manure occupying 800 square yards superficial, and divided into two equal parts. This trench is an inclined plane which rises forward and right and left, so that all the water which enters it moves down to the middle, where it collects; at that place I have a pump, by means of which I am able to pleasure to return to the manure the water which runs away from it. What water I want, I obtain from a well and pump placed by the side of the manure trench. By these means, at a trivial expense, I obtain that great quantity of water which stable-dung requires, which would in the last instance drop the water upon the ground. From the trench the water is conveyed by the time that it is taken away, unless I prefer employing it directly, and to replace it by pouring more pure water over the manure. Two halves of my trench are alternately filled from the stables. The litter is made up six or eight yards high over the whole surface of the excavation, trod down by the feet of the men who bring it and spread it, and abundantly watered by the pumps. In this way I have thoroughly made up, and as much water as I want; two conditions which I consider indispensable, in order to counteract the violent fermentation of the stable-dung, which would destroy the most artful of manures. I have added to the depth of the trench sufficient quantities of earth, which I have very carefully taken from the manure green vitriol in solution, or gypsum, so as to change into a sulphate the ammonia it is produced, and which readily flies off at a slightly elevated temperature. By means thus simple and cheap, I obtain, in seven months a manure most excellent and manured, which is composed of great energy, as is proved by the remarkable results I have obtained both on arable and meadow land for several years. When this manure, or the liquid which flows from it, is applied to land, the most striking effects are apparent. I have thus spread upon a meadow, by pouring from the spout of a watering-pot, a deep rich green, remarkable and most invigorating herbaceous turf, which has grown on the manure. (G. C. 1842, p. 20.)

1856—2284. Calcareous manures. Mr. Ruffin, a scientific agriculturist of great repute in the United States, has made many experiments with calcareous manures, and has proved the following propositions, which would appear to contribute much to the clear elucidation of the causes of the fertilising effects of lime:—

1. That soils naturally poor, and rich soils reduced to poverty by cultivation, are essentially different in their powers of retaining putrescent manures; and, under like circumstances, the fitness of any soil to be improved by lime, is in proportion to what it is deficient, in regard to this power.

2. That the cause of the natural sterility of the soils of Lower Virginia is their being destitute of calcareous earth, and their being injured by the presence and effects of vegetable acid.

3. That the fertilising effects of calcareous earth are chiefly produced by its power of neutralising acids, and of combining putrescent manures with soils, between which there would otherwise be but little, if any, chemical attraction.

4. That poor and acid soils cannot be improved durably or profitably by putrescent manures, without preliminary treatment, to render them the better to receive and retain them.

5. That calcareous manures will give our worst soils a power of retaining putrescent manures, equal to that of the best.

The proofs of these five propositions will be found at length in the Brit. F. M., new ser., vol. vll. P. 141.

1857—2307. Universal compost. The following ingredients and quantities, it is said, will afford a sufficient dressing for an acre of land:—Fifty pounds of vegetable alkali, viz., English, Russian, or American; one quart of wood-ashes; four gallons of vitriol, four gallons of quicklime, one hundred pounds, viz., two bushels, of common salt; fifty pounds, or about a bushel, of quicklime. Mix the whole together, the alkali and salt having been previously dissolved in water, and reduce the whole to such a degree of liquidity, that it may be spread from the rose of a watering-pot, as much light per ton soil as will absorb it. After this compost has lain some time, it may be carted out, and spread over the acre
to be manured; but if there is a proper water cart, this manure may be sprinkled over the land in its liquid state. (See *A Dissertation on Slts and Manures*.)

8159. *List of hand manures offered for sale at the present time (July 1843) in London*:

- Agricultural salt
- Agricultural salt, fine
- Alexander's compost
- Bleaching powder
- Bone dust, and half-inch bone
- Brimstone
- Clark's designated compost
- Danell's Bristol manure
- Guano, foreign
- Guano, Potter's English
- Gypsum
- Humphrey's inodorous soluble compound
- Hunt's new fertiliser
- Imperial compost
- Muriate of ammonia
- Murate of lime
- Nitrate of soda
- Petre, salt, 4s. per ton (See Sulphuret.)
- Phosphate of ammonia
- Phosphate of soda
- Phosphate of lime

8159. Estimate of tillage manures. "Liebig," says Professor Johnston, "broadly announced that wheat grows well in this soil, because it contains much potash, refuses to grow in that, because potash is wanting, and that the efficacy of a fallow consists in its allowing the potash of decaying minerals to accumulate in the soil, and thus to provide a sufficiency for an after crop of corn." What was this, but to say that, by adding potash to the soil, you may grow wheat after wheat for an unknown period? How important, and yet how simple, a discovery this! No wonder that it attracted the attention, and excited the hopes, even of the more instructed farmers: and that a kind of potash monomania should have spread among the distressed agriculturists from one end of the island to the other. Then was the flood-gate opened for new varieties of quackery, and every large town speedily produced its own chemical manure manufactory." (Qu. J. A., vol. I. N. S., p. 7.)

BOOK IV.
MECHANICAL AGENTS EMPLOYED IN AGRICULTURE.

Chap. I. — Implements of Manual Labour used in Agriculture. (p. 369.)

8160.—2444. *London's patent spade* has the blade case hardened, so as to remain much longer sharp than the common spade, which is apt to wear round, get blunt, or become broke. The price is little more than that of the common spade.

8161.—2444. *The under foot spade* (fig. 1142.) should be made very strong: the shaft, or handle, should be square, with the angles rounded off, and strongly plated over where it is joined to the cross-angle at top, and to the blade below. The blade is about fourteen inches across, and twelve inches deep; quite perpendicular, with sharp cutting edges, and a hilt or piece of iron (a) riveted on for the foot. For the stocking up of hedges, taking the top sods off drains, and various uses where strength is wanted, this spade will be found a most powerful instrument. (Gard. Mag., vol. vii. p. 56.)

8162.—2451. *The corn rake* (fig. 1143.), for using after the scythe, differs from the common rake both in form and dimensions. The head (a) of the corn rake should be made of fine ash; as light as possible, but strong enough to bear the driving in of a number of iron teeth; and it should be at least five feet in length, and furled with iron at both ends (b b). The teeth should be seven inches in length, and four inches apart, and so curved at their points that the weight of the rake may rest upon the curve, with the points of the teeth quite free of the ground when the rake is held in a working position. The points of the teeth should be thin and broad. The handle of the rake may be of light fir, and it should be full six feet in length. An iron (e), passing from the handle on each side to the head, will prevent the latter
from being twisted out of its position. A short handle (d), like the left handle of the scythe, and fastened at a convenient spot on the shank with an iron wedge, will facilitate the passage of the rake over the ground. (Quart. Journ. Agr., vol. iv. p. 362.)

8163. Cottam's improved dibble has two wheels which move on the axle so as to be set at any distance apart; and the dibblers on the tire can also be set at any distance, so that the implement is singularly complete for dibbling wheat, beans, mangold wortzel, &c. Figured in Johnson's Agr. Imp. 1843, p. 15.

Cottam's portable weighing machine can readily be carried by two men, and any desired weight of reaped wheat or barley or other produce can be weighed by it accurately and expeditiously. Figured in Johnson's Agr. Imp., 1843, p. 16.

8164. — 2811. The reaping-hook. It is observed by the author of an excellent article on reaping with the scythe, published in the Quart. Journ. Agr., vol. iv. p. 330., as a remarkable fact in the history of mechanical science in Britain, that the art of cutting down corn crops should be so inadequately supplied with instruments. The reaping-hook, unlike every other mechanical instrument, depends entirely for its efficacy on the physical powers and dexterity of the labourer. The knife and the spade are as simple in their construction as the reaping-hook; and yet the former has been displaced by many mechanical contrivances, while the reaping-hook remains in all its primitive simplicity. Its continued use in the field is attended with immediate loss of time and money; and therefore an efficient reaping-machine is invented, it is proposed to substitute, in many cases, the scythe in its stead. The scythe is used, for this purpose, in France, Switzerland, and in many parts of Aermshire, and it appears to be gaining ground everywhere.

8165. — 2810. Howe's two-edged bill-hook (fig. 1141.) This hook is something like the letter S: it is all round sharp, and combines the powers of the carpenter's axe, the gardener's knife, the hege's hook, the Highlander's broadsword, and the joiner's chisel. The blade is twelve inches in length, and three inches broad; the socket is eight inches long, and serves instead of a wooden handle when the instrument is used as a knife, bill-hook, or axe; when it is to be used as a chisel, it must be placed on the end of a long handle; and will then, either by pushing or drawing, remove small branches from the stems of tall trees. The long socket is made a little oval in the direction of the two edges, in order to let the operator feel where the edges are. The chief use of this instrument, however, is for dressing hedges, and for that a wooden handle, or handle, of about two feet in length, is best. (John Howed, April 20, 1830.)

8166. — 2810. To preserve hedge-bills, scythes, sickles, and other steel instruments, from rusting, wipe them quite dry, heat them sufficiently to melt common bees' wax, and then rub them over with it so as to cover the whole. The wax, when it has cooled, is not susceptible of rust, and prevents any decomposition from taking place on the surface of the steel; and when the instrument is wanted for use, the wax is readily removed by the application of heat. (G. M. 1839, p. 186.)

8167. — 2810. Grazer's sliding rule for showing the weights of fat cattle, was invented by Dr. Wollaston for Lord Spencer, and may be considered as an essential article for every cattle dealer. (Journ. A. E., vol. iii. p. 337.)

8168. Cottam's dynamosmometer is so arranged as to obviate the continual vibration of the pointer usual in such instruments. This is effected by a cylinder filled with oil, which is furnished with small apertures in it, the rod of which is attached to the pointer. The obstruction caused by the oil to the quick passage of the piston, prevents any slight alteration in the draught from influencing the pointer, unless the increase or decrease is continuous, when it will immediately indicate the mean draught of the machine on trial, and not the draught of any temporary impediment, or cessation of resistance. (Johnson's Agr. Imp. for 1843, p. 15.)

8169. Clybar's dynamosmometer, records on a roll of paper the distance which the plough or other implement may have passed over, and the weight necessary to draw it through all its variations. (See Johnson's Agr. Imp. for 1843, p. 37.)

8171. — 2814. Wire turnip baskets, as a substitute for those of willows, in carrying turnips to feeding cattle, are recommended by Mr. Buist in Q. J. A., vol. xi. p. 112.

8172. — 2814. Slight and Lilie's straw-cutter (fig. 1145.) is considered to be the most perfect machine of this description that has hitherto been invented. In most of the other machines, the oblique position of the cutters, relatively to the hay or straw which they have to pass through, is found to be attended with difficulties to the workmen when replacing them after they have been taken off for sharpening. Messrs. Slight and Lilie have obtained the advantages of passing the knives in an oblique direction through the body of hay, without occasioning the slightest difficulty when these knives are removed to be ground. This is done by elongating the cutting-box into a nozzle, which is twisted out until its orifice assumes an angle of about thirty degrees. In this arrangement, the entire efficiency of the machine is retained, while its construction and keeping in order are simplified, and its price is proportionately reduced. The framing is made entirely of cast iron: a is the feeding-trough; the rollers being only partially seen; b is the nozzle or cutting-box: c e, the cutting bearers, with the cutters attached by means of bolts, washer, and weight, which, through the medium of the bridge e, keeps a constant pressure on the feeding-rollers to counteract any inequality of feeding: f is the fly-wheel for equalising the motion; and g, the handle to which the power is applied. The small pinion on the fly-wheel shaft gives motion to the spur-wheel, which is mounted on the shaft of the lower feeding-roller, and carries also the lower feeding-pinion. This last pinion works into the pinion of the upper roller; and both, being furnished with very long teeth, they thereby admit of a limited range of distance between the rollers according to the quantity of feed. With one of these machines, a man, assisted by a boy to feed the hay or straw, can cut
at the rate of eight stones per hour; and that quantity of cut hay is found to be sufficient for sixteen horses for twenty-four hours. (Quart. Jour. Agr., vol. iv. p. 349.)

8173—2568. Taylor's tub for measuring and weighing corn, represented in figs. 1146, 1147. The tube \((a)\) has a movable bottom \((b)\), which, when it is desired to let the corn drop out, is raised by putting the foot on the pedal \((c)\) which operates on the lever \((d)\). The valve is worked by a spindle, which passes through the collar \((e)\). The angles at the bottom of the tube are bevelled off to allow of the free egress of the corn into the sack below it. Of course the tub should be suspended high enough above the floor to allow the corn to escape; and for this purpose a platform \((f)\), ascended by steps, is required, which may be either fixed or movable. Up this platform the man walks who bears the sack of corn; and the mouth of the sack being previously untied, he shoots the contents very gently and gradually into the tub. The precaution of shooting the corn into the tub gently and gradually is essentially necessary, as otherwise there will not appear to be full measure. The mode of weighing may be either by Marriott's dial engine, or by a steelyard beam; the former is the most simple. This tub was invented by Mr. Samuel Taylor, and is used in the extensive malting establishment under his care at Stokelerry, Norfolk. (Gard. Mag., vol. viii. p. 467.)

8174—2571. Baird's turnip-slicer (fig. 1148.) Is considered one of the best turnip-slicers in use in Scotland. It is made, when of full size, entirely of cast iron, and consists of a standard or frame to which is attached a hopper; the frame bearing a circular plate of cast iron mounted on a horizontal axis, to
which the winch-handle is attached. This plate is cast with a thickened edge or rim, which gives it, when in motion, the effect of a fly-wheel. It carries two thin cutters or knives, set parallel to the face of the plate, and radiating from the centre. The thickness of the slices is regulated by the distance of the knives from the face of the plate. Each knife is preceded by three or more lancet-pointed studs, which, by slitting the turnips in passing, prepare the slices for falling in pieces when they are detached from the knives, at each revolution of the plate. This process goes on so long as the hopper is replenished with turnips, their own weight being found sufficient to hold them within the stroke of the knife. When potatoes are to be sliced, the disc above described is to be removed, and another substituted, differing from the first in having the cutting studs set closer together. In the figure, a represents the hopper filled with turnips; b, the disc of cast iron that carries the cutters; c, one of the cutting knives, the opposite one being concealed by the framework; d, the lancet-pointed studs; e, the winch-handle, partially seen from behind the machine; f, the framework of the machine; g, h, two bars which slide into staples, and serve as handles by which it can be removed from one place to another. (Highland Soc. Trans., vol. x. p. 51.)

8175. The lever turnip-slicer (fig. 1149.) has lately been much improved, and in Scotland is taking the place of more elaborate machines. "The advantages of this form of slicer are, 1st, the certainty of turning turnips free of even the smallest portion of waste, a property which few of the revolving machines possess in such perfection; 2d, Its cheapness, the price being only from 20l. to 30l.; 3rd, its portability, being easily carried about by one person, or it may be mounted on wheels at a small additional expense. It has the disadvantage of being only capable of cutting slices, and therefore not so well adapted for sheep feeding, but it is quite as expeditious as some of the revolving machines, as a man or a boy will slice 10 cwt. of turnips in ten minutes with this machine."

8176. A turnip-sowing machine, which sows two rows at a time, and deposits along with the seed a regular train of bone-dust, is described in the Quarterly Journal of Agriculture, vol. ii. p. 718.

8177. A machine for sowing carrots was invented in 1833, by Mr. Daniel McNaughton, farmer, near Irvine, in Ayrshire. Fig. 1150. exhibits the general appearance of the machine, which is similar to those in common use for sowing turnips; the essential difference lying in the apparatus adopted for discharging the carrot seeds from the seed-boxes. To the lower part of the framework is attached, in the usual manner, the great roller (a) serving to compress the prepared ridgelets, and also to communicate motion to the other parts of the machine. This is effected by means of a leathern belt or a pitch chain, passing over a pulley at the extremity of the roller, and another of the same diameter at the extremity of the axle (b); which last, in the common machines, always carries the seed-boxes, but in this performs a double purpose. The first of these purposes is, that by means of two pulleys, which are not seen in the figure, it gives motion to two other pulleys (c) of the same diameter, mounted on small axles, which pass through the seed-boxes, and are each mounted with three plain wooden pulleys; the middle one is about six inches in diameter, one inch thick at the centre, and is diminished to about half an inch thick at the edges; the other two are three inches in diameter, and of proportional thickness. The middle pulleys, unseen, are armed with six stout wire prongs, the extremities of which describe a circle of twelve inches in diameter; while the smaller pulleys (at e) are similarly armed with five prongs, extending to seven inches in diameter. The revolution of these armed pulleys keeps the seeds in continual agitation preparatory to their being propelled from the box. The second purpose to which the axle (b) is applied, is to carry a small wooden cylinder, placed immediately under each seed-box, of five inches in length, and three inches in diameter, armed with four prongs or claws, extending to a radius of three inches. In the revolution of these claws they penetrate successively into the orifice of the seed-box, and perform an operation of picking or scratching out the seeds in a regular succession. The seeds are received into the funnels (i, i), and pass from thence down the tubes in the usual manner to the ground, where a rut is prepared for them by the couter. The seed-boxes are made of sheet iron, or of tin plate, of an elliptical form in the mouth; the diameter being about eighteen inches and twelve inches, with a depth of twelve inches; the cross section, taken either longitudinally or transversely, being also elliptical. The bottom of the box terminates in an oblong orifice of about six inches long by half an inch wide in the clear; the latter dimension being capable of extension, or diminution, by means of two pinchling screws. Each box is covered with a movable lid, to prevent the seeds from being thrown out by the agitators. The funnels, with their seed tubes, are attached to the hind part of
the coulters, and are provided with an adjustment, by means of the slits and pinching screws in the collar bar (k) of the framework, enabling the operator to regulate the distance between the rows, while, by means of the slits and pinching screws (m n), he can regulate the depth of the furrow for the seed-bed. The machine is convertible into a turnip drill by a very simple alteration. The seed-boxes and the claw cylinders are removed; and, in place of the latter, two barrel-shaped seed-boxes of the common construction are substituted upon the axle (6). It is then a complete turnip drill-machine. When, again, it is required for sowing onions, the turnip seed-boxes are removed, as also the collar bar. The axle (6) is then mounted with five barrel-shaped seed-boxes, similar to, but smaller than, those for turnips. A collar bar, with five permanent coulters, is placed in the slits (l) of the frame. The coulters are perforated from top to bottom for the passage of the seed, terminating in the hind part of the lower extremity. Five funnels, corresponding to the seed-boxes, are inserted, one into the upper orifice of each coulter, and thus the machine is prepared for sowing five rows of onion seed. (Highland Soc. Trans., vol. 1. p. 293.)

817. — 2578. Crosskill’s improved turnip drill, with apparatus for saving boxes, ashes, &c., is considered a very efficient implement, and is much used by those who apply the manures commonly called hand-tillages. The price for one row drill, 6l. 10s.; and for two rows, 9l. 10s.

818. — 2579. Implements for compressing flour or meal into cake. A machine used for North America, and it will be found described in the Quart. Jour. Agr., vol. iii. p. 559.

8180. A machine for compressing peat (fig. 1151.) has been invented by Mr. Walter Tod, of Longhope, near Hawick. The same machine might also be employed for compressing earth for building walls, and for other purposes. A more powerful and elaborate machine has been invented by Mr. Slight, the Curator of the Highland Society’s Museum of Models, and figured and described in the fourth volume of their Transactions; but the simple machine of Mr. Tod, we think, will be more useful in countries where the fuel is peat; and in new countries, where the eminent might think it advisable to build the walls of his houses. This machine consists of a set of wood planks, consisting of a bottom end by cross bars, and mounted upon four wheels. Two pieces of wood (c, d) at the distance of two inches from one another, are mortised into the plank (a, b) at the end a, and at right angles to b. Between the upright posts (c, d) there is inserted a strong beam (a, c) twelve feet long, and secured with an iron bolt passing through the pieces (c, d), which have numerous holes to admit of raising and depressing the beam (a, c) at pleasure. Two boxes are then made, one of wood, and one of sheet iron fourteen inches in length, three and a half in breadth, and three and a half deep. These boxes have lids which just fit them, about three inches in thickness, to allow them to sink to the boxes by the pressure. Each box is to be alternately filled with peat newly dug, the lid adjusted, and the box placed in the machine at the point f; a man stands at the end (c) of the beam (a, c); and, as each box is placed in the machine at the point f, he bends the whole strength and weight upon the end of the beam. By this means, an immense pressure is applied to the box by a single effort, and in an instant of time. Two women may fill and remove the boxes. In this way a man and three women could compress about eight cart-loads of peat in a day. One man digging, and a woman throwing out the peats, could keep the machine in full operation. The peats, when taken from the machine, are built up like small stacks of bricks, but so open as to admit a free circulation of air. The stacks put up in this way become perfectly dry, without being moved till they are taken home. If the machine just described were to be adopted for compressing earth, boxes of cast iron, fitted with small holes, would answer the purpose best. The pressure is so great, that the wooden boxes frequently give way, though strongly made, and secured with iron at the ends; and even the one of strong sheet iron has been bent. (Highland Soc. Trans., vol. ix. p. 574.)

CHAP. II. — Implements and Machines drawn by Beasts of Labour. (p. 383.)

8181. — 2908. Swing ploughs on Small’s principle. Notwithstanding the numerous swing ploughs that have been brought into notice within the last seven years, the best practical agriculturists who follow the Scotch system, such as Morton and Donaldson in England, and Oliver, Professor Low, and Mr. Stephens in Scotland, seem to be of opinion that the improved Small’s plough has not yet been surpassed. It would appear, however, from experiments reported in the Journal of the English Agricultural Society, vols. iii. and iv., to be afterwards quoted, that there are some ploughs, both with and without wheels, which are drawn through the soil with less power than the best Scotch ploughs. We do not, however, consider the result of the trials which have been made as warranting us in recommending any other swing plough in preference to Small’s. The best forms of this plough, according to Mr. Stephens, are: the East Lothian or Small’s plough, the Lancashire or Wilkie’s plough, and the Mid-Lothian or Currie plough. The best makers in Scotland are Wilkie of Uddingdon, near Glasgow, and Clarke of Stirling. (Stephens’s Book of the Farm, vol. 1. p. 107.)

8182. — 2909. Wilkie’s turnerest or hill-side plough (Trans. Hort. Soc., vol. xii. p. 484.) (fig. 1152.) as always used by Mr. Smith of Deanston. These fields, being thoroughly drained, have a regular uniformity about furrows. Each of the two mould boards in this plough is attached to the rod b, by two bands of iron, c, c, by which, with the end of the handle d, they are alternately raised or depressed; while the one is in a working position, the other is carried above. The rod b, extending to the coulter at f, in moving the mould-board, moves also the coulter one inch at the point, so as to give it the proper position with the point of thenock a. (fig.)

8183. — 2916. The Deanston subsoil plough (fig. 1153.), as designed and used by Mr. Smith on the farm of Deanston, has been found peculiarly efficacious in rendering productive a sterile soil upon a tenacious
bottom. It has been constructed so as to be of easy draught, and to penetrate to a depth of from sixteen to eighteen inches from the surface. It has no mould-board, and is intended merely to break and stir up the subsoil, without bringing it to the surface, or mixing it in the first instance with the incumbent soil. It is, in fact, a horse-pick, and readily loosens and throws out all stones not exceeding seventy-five pounds. The chain for the leading horses to draw by, is about 94. The ordinary swingle-trees and harnessing suit, with straps over the quarters of the leading horses, to bear up the swinging view to their butts, and a chain from the collar of the hind horses to bear up the soam chain. Th is plough, with four horses, a ploughman, and a lad to drive, will do about an acre imperial per day, at a cost of about £1.; no charge being made for the common plough, as the land would require a furrow at any rate. Such ploughs are made by Roberton Smith, at Drip (Dundee). It is drawn by fourteen horses, two and two abreast, and it is held in the usual way by one man. In working, the common plough goes before it, taking a furrow ten inches by six inches, the subsoil plough following in the bottom of that furrow, and going deeper by ten or twelve inches. When this plough is applied on a slightest attention, in the construction of the subsoil plough by Mr. Armstrong, whose implement combines a common plough and a subsoil plough, and is considered an important boon to small farmers, as facilitating among them the system of subsoil ploughing.

8152. Wilkie's improved friction wheel plough for two horses. The invention of the friction wheel plough is claimed by Mr. Morton, an implement manufacturer of Leith Walk, Edinburgh, who "conceived the idea of introducing a wheel into the body of a beam of the common plough, about fifteen inches in diameter, to act as the sole," so far back as 1812. The average draught of the ploughs when the wheel was applied was reduced about one fifth, or to about two cwt. and three quarters. He manufactured a number of these ploughs both for home and foreign use; but in a short time, the farmers in the neighborhood of Edinburgh left them off, giving as a reason for so doing, that they required more attention from the ploughmen to grease the axle of the wheel, than the latter were willing to give. (Gard. Mag., vol. vi. p. 200.) We may notice it, as a remarkable circumstance, that Professor Low, in his Elements of Practical Agriculture, published in 1834, describes only Small's plough, without mentioning Morton, Wilkie, or any other inventor, and without inspecting the subject of wheel ploughs of any kind. The invention of the friction wheel is also claimed by Mr. E. Elliott, who lately managed a farm near Shepperton, in the county of Middlesex. In the Farmer's Journal for August 15, 1831, an account of an experiment is given in which Wilkie's improved plough without a friction wheel was tried against the same implement with a friction wheel, and both against the common swing plough in use in Middlesex. Wilkie's plough, without the friction wheel, required four cwt. two quarters; with a friction wheel, three cwt.; and the common Middlesex swing plough, six cwt. Notwithstanding experiments of this kind, it is an undeniable fact, that the old, heavy, clumsy Middlesex plough, which it appears requires twice as much strength to draw it as Wilkie's friction wheel plough, is still that commonly used in the county! We cannot suppose that any class of men would persist in a practice which they knew to be decidedly opposed to their own interest, and therefore we unavoidably conclude that in ignorance, or prejudice, or both, we must seek for the cause of these men so obstinately adhering to the practice of their forefathers. The truth is, as we have elsewhere observed, the farmers are the only class of Englishmen who do not read.

8153. Pearson's draining plough has been used extensively by Sir C. M. Burrell in clayey soil, at Knapp Castle, near Horsham, in Sussex, by which the land has been increased in value one third. The drains are made in parallel lines about 8} feet apart; they are from 24 inches to 26 inches deep; a tile is laid in the bottom; and, charging at the rate of 2½, a day per horse, the total cost, the tiles being made on the spot, is about 52s. per acre. (G. M. 1840, p. 102.)

8154—2019. Comparative estimate of ploughs by English agriculturists. Scotch agriculturists, with scarcely any exceptions, consider the Scotch swing plough as preferable to all others; but since the establishment of the Agricultural Society of England, a number of experiments have been tried with wheel ploughs and swing ploughs of various kinds, and the general result are, that certain wheel ploughs are of easier draught than swing ploughs, and that some English swing ploughs are of lighter draught than Scotch swing ploughs. The progress of the inquiries of the English Agricultural Society is thus summed up by Mr. Pusey in an article published in November, 1812:—"At the time of our foundation, four years back, the Scotch iron swing-plough was stated to be the most perfect form of plough. Lord Spencer having remarked that, from his observation of ploughing-matches, he doubted whether swing ploughs had any advantage over those with wheels, a prize was proposed by our council for the best essay upon the subject, which was won by Mr. Hanley, who applied the
supplement.

SCIENCE AND ART OF AGRICULTURE.

1317

draft-gauge for measuring the strain arising to the horses from different ploughs, and found that those wheel ploughs he tried inflicted the least labour upon the cattle. Following his example, I tried several ploughs in the same manner, and with the result that there was a much wider difference in the draught of ploughs than had been suspected, and even that one wheel plough used by two farmers in the same parish and on the same soil, one was heavier for three horses than the other for two; the old Berkshire plough costing the cattle a muscular strain of 25 stones, while Hart's improved one-wheeled plough was drawn by them with an effort of only 14 stones at most. Ransome's was hardly surpassed by Hart's in lightness, and it certainly made better work. The Scotch were the heaviest of the swing ploughs. The next trial was made by Mr. Freeman at Haverton in South Wales, who set up an old Welsh plough of the cruciform variety, and, as it appeared, the old ploughs were much less severe for three horses than Hart's was for two. The old plough stood at 20 stones; Hart's at 13. The next experiments were made by Lord Tweeddale, and in these the Yester plough equalled Hart's plough in lightness. The next trial was before our judges at Liverpool, and I will quote from their report: 'It appears that in almost every case the draught of the wheel plough was less than that of the swing kind; and it must not be concealed that the wheel ploughs in every case actually turned over more soil than the swing, for the share and sole of the former maintained a flat, horizontal position, whereas all the swing ploughs turned more or less less into a kind of a ledge on the left-hand side. Consequently the furrow-bottoms left by the wheel ploughs were more than those excavated by the swing ploughs.' On this occasion, a wheel-plough by Messrs. Barrett, of Reading, was the lightest, marking 22 stones; Hart's the next, 24 stones; the ground most ploughed the heaviest, standing each at 40 stones. I cannot but remark how little our mechanists yet know of the draught of their ploughs, when implements could be brought forward to compete for a prize at a great public meeting, some of which gave as much work nearly as four horses as others for two. The latest published record of trials is a very careful set of experiments by Mr. J. M. Lankester, in Oxfordshire. Here again, as in Wales, and in Berkshire, the lightest plough stood at 13 stones, the old Oxfordshire plough at 22 stones, the Scotch swing-plough at 20 stones. The lightest plough in this instance was Messrs. Barrett's. There only remains the report of our judges on the ploughs which competed at our Bristol meeting. There, again, it will be seen that the lightest plough was a wheeled one, a Mr. Howard of Bedford, which stood at 22; the heaviest, a Scotch swing plough, marked 90 stones. Of the swing-ploughs the Scotch swing and those marked by the words of our judges, it is worthy to note that the resistance of Mr. Howard's two-wheeled plough was less by 44 than that of his swing plough. From these repeated trials, which have arisen out of Lord Spencer's remark, we may now come to the conclusion that wheel ploughs, as he suspected, are superior to swing ploughs, in ease for the cattle, and are also superior in the work they perform, that the Scotch swing plough in particular is very severe for the cattle; that, since in three country trials the draught of the ploughs was found to differ as two to three—that is, as two horses to three—more attention is required on the part of the ploughmen to their draught, and still, the interesting point here, that in the recent competitions at Liverpool, and again at Bristol, the draught of some competing ploughs doubled that of the winning plough, it appears very clearly that our ploughmakers, as a body, are not thoroughly acquainted with the qualities of their own implements, otherwise the race could not be so unequal."

8157. Comparative estimates of ploughs by Scotch agriculturists. Notwithstanding the experiments made in England under the auspices of the Agricultural Society seem to prove the superiority of wheel ploughs, many in favour of swing ploughs are found in favour of the ploughs in use in Scotland. Mr. Slight, in Stephens's Book of the Farm, observes, writing in 1822, "no ploughman who has been able to wield the swing plough will ever suffer himself to be incompatibly with the addition of wheels to his plough (for he will always consider what I mean by an improvement) the reduction of the draught inferior to that of any part of the kingdom, and as the chances are surely equal that the ploughmen are not all equally good, it is evident that ploughing can be satisfactorily performed without wheels. If ploughing can thus be performed over one part of the kingdom with the plough of the simplest form and in the same manner, there can be no question of the superiority of the more expensive and more expensive machine to perform the same work in another part of the kingdom, where it is at least not better done or done at less expense." (Stephens's Book of the Farm, vol. i. p. 643.)

It has always been considered at Ledyard's, at the works at Uley, in Gloucestershire, and known as Lord Ducie's, or the Uley cultivator, is recommended as the best; and, from the description, it appears to be an admirable implement, and by far the best of its kind which has yet appeared. It has been tried for paring as well as pairing, and is perfect. (Johnson's Agr. Mag. 1849, p. 31.)

8159. Bucknalle's horse-hoe, for hoeing and thinning turnips (fig. 1151). The idea of an implement of this kind occurred so long ago as 1778 to Mr. Skirling, of Strathruddy, in Fife-shire, one of the Scottish
martyrs, but we are not aware that it was ever before realised. A set of revolving blades in this hoe work across the rows of turnips, leaving the plants at regular distances. (Johnson’s Agr. Imp. for 1843, p. 57.)

8191.—2090. Crosskill’s broadcast manure sower (fig. 1156), which is drawn by one horse, will contain 8 bushels of manure in a state of powder. It is 6 feet wide, and can be regulated so as to deposit the manure at any given rate per acre. By placing the drill box in a vertical position the quantity of manure sown is increased, and the contrary by placing it in a horizontal position. Price 12l. 12s.

8192. Cottam’s improved serrated chain harrow (fig. 1157.) consists of a number of serrated iron discs interwoven and linked together with iron rods, the whole forming a surface of thirty superficial feet, interspersed with nearly four hundred points or discs. It is said that no clod can escape the influence of this harrow, and that it will be found particularly serviceable in harrowing after seed has been sown. (See Johnson’s Agr. Imp. for 1843, p. 17.)

8193. — 2700. Crosskill’s clod-crusher roller (fig. 1158.) is intended to effect the same objects as the spiky roller. It consists of a number of segments fixed on an iron axle six feet six inches long. Ploughed land once rolled by this machine is said to be reduced to a finer state than by two or three rollings and harrowings with the ordinary machines. It is drawn by three horses, and cleans itself, even when land is in the very roughest state. A number of these machines have been manufactured by the inventor at Beverley, and used by the farmers of the surrounding country. The price of a machine, including two iron road wheels to attach to it when not in use, is from 17l. to 19l. delivered in Hull. Mr. Crosskill...
informs us (June 22, 1843) that the demand for this machine is from 150 to 200 annually. For the first two or three years after it was invented, he did not make above 2 or 3 annually.

Mr. Crosskill's Improved Scotch cart (fig. 1160) holds 120 gallons. The body, a, is made of cast iron; there is a brass valve lever, f, by which the liquid may be let out by the iron spout, c, upon the spreading board, d, and a patent iron pump, b, which cannot easily choke or get out of order, with a flexible hose, of 1 inch bore, and a 3 feet copper pipe, c, seven feet long, with a 3 feet copper pipe at the end for drawing up the liquid from the monopol tank. Another improvement is an excellent machine. The price delivered in Hull is 22s. Dean's liquid manure cart figure in Johnson's Agr. Imper., p. 32., appears also to be a very excellent machine: cost complete, 3s.

An Improved and useful water-cart was described by Mr. Hunter in the Farmer's Magazine, vol. viii. p. 81. — A barrel, holding 100 to 200 gallons, is the usual pair of wheels and is placed in the usual way. A pump, three inches in diameter, is placed close by the side of the barrel, and under the end of the pump is made fast a leather pipe of indefinite length, with a rose copper end, and in the pipe small copper or tin rings are placed, to catch any moisture that may escape from the external air from pressing together the sides of the pipe, and thus excluding the water. The cart being placed on the bank of a river, brook, or pond, and the pipe thrown into the water with the rose end immersed, a man will pump 150 gallons in ten minutes, without the trouble of having a road into the bottom of the river, and with the great advantage of the horse standing dry, and not plunged into three feet of cold water on a winter day, in the usual way of filling by ladle and standish. A stop-cock is fixed behind for discharging the water. When the cart is to be moved, the leather pipe, b, is placed, fastened, by two iron catches. The barrel being filled, and driven to the place required, the leather pipe is immersed in the barrel by a hole in the top, sufficient to admit the rose end. A small iron rod screws down by the side of the piston rod, upon the upper valve, and shuts in fast. A rising main, with a check valve, is opened between two pipes, upon which lies a leather pipe with a copper tube on the end. One man directing this pipe, and another pumping, converts the cart into a sort of fire engine, that may be very useful in cases of emergency, throwing the water forty feet horizontally, and over any house or corn-stack, and is also very useful for garden walls and fruit trees. By increasing the size of the barrel, and by applying more power, a very sufficient engine may be made, and answering other purposes at the same time.

Man's reaping machine was invented in 1829, but neglected till 1859, when it was improved; and in 1852 it was exhibited at an agricultural fair. It differs from Bell's reaping machine in being drawn instead of being pushed, and in depositing the corn in a continuous swath near right angles with the line of direction, and on the side opposite to the standing corn. Both these are advantages which we hope will not be lost sight of by the mechanism of Bell's, which may be produced in the present time making such a reaping machine as shall come into general use. An engraving, with descriptive details, of Man's reaping machine will be found in the Quart. Agr. vol. iv. p. 250.

An improved corn and hay cart is exhibited in fig. 1160, and is in general use in the neighborhood of Kirkcudbrightshire. The advantages are, a great simplicity of structure, and what constitutes its chief excellence, the load takes its rise at the very commencement of material, by which the centre of gravity of the load is brought lower than in either the common corn-cart, or the dung-cart with top-frame, wherein a greater degree of strength and safety against the risk of upsetting is acquired, and a greater facility of loading. Another advantage may be pointed out in the case with which it is converted into a cart for the conveyance of timber, by simply unlashing the frame from the shafts, and in its place laying two single cross bars, one before, and another behind the wheels."

"Thus machines are everywhere very imperfect, even in Scotland, where they were first invented, and where machines of the largest power, impelled by water or steam, are erected at great expense. The editor of the Quarterly Journal of Agriculture has the following judicious observations on this subject: — 'We were thrashing machines constructed on correct and unerring principles, like the machinery of a timepiece or of a steam-engine, even if a flour-mill, the advantage to the farmer would not only appear in the shape of cleaner threshed straw, and of economy of time and labor, but the millwright himself would derive great advantage in the certain possession of material, with which to enable him to construct thrashing machines that would suit the particular localities in which they were to be placed. There is no way of arriving at this perfection, but by the institution of experiments to ascertain what may be the simplest construction of the thrashing machine, and that which will produce the least quantity of moving power to execute the desired work satisfactorily. These desiderata would produce the advantage of threshing the corn at the least cost. Thrashing machines are of so durable a nature that they are not often renewed; but for that very reason they should be constructed in the best manner at first. A set of patterns would be made in the neighborhood of Kirkcudbrightshire, making it very convenient for carrying in the sheaves: the second one contains the first winnowing machine; with a chaff-house, partitioned off under the stair, and
descending to the floor below, with a door into the straw-house, and one into the cattle-yard. When the corn is only to be passed through the first winnowing machine, the corn elevators and second machine are thrown out of gear, and the corn delivered on the second floor, where the bruising machine is fixed. The under floor contains the second winnowing machine with the lower end of the corn elevators. If necessary, the clean corn may be delivered on this floor, instead of into the elevator trough: the ends of both machines are inserted in the chaff-chamber. The corn is put between two grooved rollers, when the grain is beaten out of the ear by four beaters fixed on the threshing cylinder, and thrown into the rake or first shaker, when it falls through the sparrowed bottom into the winnowing machine hopper, while the straw is raked forward and thrown upon the travelling shaker, where it is thoroughly shaken, and conveyed into the straw-house. This is a very useful appendage to a threshing-mill; it takes all the refuse from the fanners, which generally accumulates about a barn floor (or is carried up by hand), whereas the elevators carry all away, and thereby leave a clean barn. The corn passes through another pair of fanners, and from thence into the corn elevator trough, and is carried from thence into the granary and thrown into the weighing machine, which is connected with an index in the barn on the partition wall facing the man at the feeding-table, which shows the quantity threshed very nearly. The machine occupies part of three floors. The water wheel is in a house beside the barn, and in a room above the wheel is a Scotch barley-mill, and beyond it is a very complete saw-mill, both driven from the same wheel, which can be detached when the threshing part is at work, and is an oat bruiner driven from the upright shaft; it can be put out of gear if wanted.

**Description.** In figs. 1161, 1162, 1163, a is the water-wheel, eighteen feet in diameter by four feet wide; b, a pit wheel, eight feet in diameter, which works into a pinion, c, of fifteen inches in diameter, fixed on the upright shaft; d, a bevel wheel, five feet in diameter, which turns the drum pinion, e, of nine inches in diameter; f, the drum, or threshing cylinder, three feet four inches in diameter outside of the beaters, and four feet and a half long, with four beaters turning upwards with a velocity of 300 revolutions per minute; g, a bevel wheel, twenty-one inches in diameter, turning a pinion of five inches in diameter a quarter-diameter, on the axle of which is another pinion five inches in diameter, working in the face wheel, i, with two rows of teeth, one of thirty and the other twenty-four teeth; this pinion slides along its axle into either set of teeth; for instance, into the one of the smallest number if the straw is short, loose, and irregular. The rollers are about three inches and a half in diameter; the wheels g and j are each twenty-one inches in diameter, working into the pinions k k, five inches and a quarter in diameter, which gives motion to the rake or first shaker at the rate of forty-four turns per minute; it is four feet in diameter to the extremity of the teeth; I I, two wheels, each twenty-one inches in diameter, with pinions, m m, five inches and a quarter each, which drive the travelling shaker that receives the straw from the rake, and conveys it into the straw-house. This shaker is composed of two endless pitch chains, worked by two stud wheels ten inches in diameter, with eight studs on a quarter-diameter shaft, the same shaft as the wheels m and n, revolving at forty-five times per minute. These chains are kept stretched by two smooth wheels at the further end in the straw-house: between the chains are fixed round wooden rods about two inches apart. u is a wheel with large teeth on its circumference, which is circumferently, as it turns round, depresses the point of the lever o, and raises the end p. The lever is fixed on an axle which passes through to the other side of the shaker, with a short lever fixed on it to correspond with the lever p; on these levers, p p, rests a small shaft, on which is fixed on each end, under the chains, a small drum four inches in diameter, which supports the shaker in the middle, as the wheel, u, moves round. The point of the lever, o, strikes from tooth to tooth, and thereby keeps the small shaft, at p, in motion up and down, which shakes the loose corn out of the straw, which is drawn back by the under returning rod into the winnowing machine hopper; q is the first winnowing machine hopper, which contains the winded winnowing machine; both driven by a small water-wheel, six feet in diameter, and four feet wide; the water from the large wheels supplies this one. The motion of the machine requires to be uniform, which cannot be the case if connected with the threshing part. It answers better to have a separate wheel for
The clean corn passes into the elevators; from thence it is carried up into the granary, and delivered into the weighing machine, 1, by small elevators made of sheet iron, with wooden backs and bottoms fixed to a pitch chain, revolving round a studded wheel ten inches in diameter, and with eight studs at the upper end, and a small wooden roller at the bottom, at eleven turns per minute.

The corn is delivered into the weighing-machine box, 1, and accumulates until there is the weight of a measure, when the box turns on its axle, and the corn is emptied into the spout which conveys it into whatever binn it may be wanted in. At the same time the part 2 turns up, and is filled as the other, and, when full, descends as the other, and so on, while the threshing is going forward; 3 is a weight which slides up and down a rod fixed at right angles from the bottom of the weighing machine; if the corn is heavy, slide this up until it will balance a bushel of corn similar to what is to be threshed; if light, slide it downwards. From the axle of this box, a small rod proceeds to two small wheels behind the index, a, which turns two fingers that revolve round the face of this index; it is figured from 1 to 10. For every movement the weighing bucket makes, the longest finger moves over the space of one, and for every ten, the other finger moves one. At the end of the threshing, this finger will denote pretty accurately the quantity threshed; for instance, were the long finger at 5, and the short one at 3, there would be ninety-five bushels of corn in the binn; \( xx \) are pinions five inches and a quarter in diameter, each working in wheels \( yy \) twenty-one inches in diameter each, which give motion to the corn elevators, and likewise to the tail elevators by a pitch chain revolving round the stud-wheel \( w w \), giving motion to the shaft of the elevators at eleven times per minute. The buckets are made of thin boards fixed on two pitch chains turned by two stud wheels ten inches
in diameter at the upper end, and a wooden roller at the lower. (J. Gladstone, Lead-works, Chester, Oct. 29, 1831.)

8202. Mr. J. Gladstone, civil engineer, Chester, to whom we are indebted for the foregoing plans and description, with reference to the improved form of the threshing machine, says, "I have always understood that it was to my father we are indebted for it in its improved state. In 1788, Mr. Andrew Meikle produced the first machine of the kind, for which he took out a patent. (See Repository of Arts, vol. x. No. 58.) This was simply a threshing cylinder with the beaters turning downwards, throwing straw and corn into a moving screen, which separated them in a very imperfect manner; so much so, that I have heard the machines were given up, or going into disuse, simply on account of the beaters striking downwards; if the ears escaped the beaters immediately on passing through the rollers, they were bent under them, and laid close to the interior of the cylinder case, and thereby evaded the stroke of the beater. In 1793, my father made his first machine, similar to that of Mr. Meikle, with this difference, that the threshing cylinder turned upwards, and as the corn came through the roller, it lay upon the cylinder, and, being exposed to the stroke of each beater, escaped being threshed." (See The Stewarty of Kirkcudbright Agricultural Report of 1810.)

8205. The late Mr. Gladstone, of Castle Douglas, added the shaker to the threshing machine in 1794, and what he called a letterer, for breaking off the awns of barley, soon afterwards. In 1798, he made a threshing machine, to be driven by windmill sails. In 1799, he invented the draught chains used in threshing machines, to equalise the pressure of the draught on the horse's shoulder. In 1805, he added a travelling shaker to the threshing machine, and soon after, a contrivance for conveying the corn from the fanners into the gruary, and weighing it at the same time. By another piece of machinery, the corn may be accurately measured. "On reviewing the whole," he writer, in the Report of the Stewarty of Kirkcudbright Agricultural Society for 1816, observes, "it is impossible not to perceive how vastly superior the machines of Mr. Gladstone are to those first contrived by Mr. Meikle, and what distinguished services he has thus rendered to the interests of agriculture. The machine is now constructed on the basis of the threshing not only of one, but of every, species of grain. It is adapted of itself to separate the straw from the corn, and convey it perfectly shaken into the straw-house; to clean the corn effectually; to weigh and measure it accurately; and to lodge it securely in the granary. Of late years, by the adoption of the chain bucket outer wheel saves an inner one, formerly deemed indispensably necessary, and simplifies the machinery: if by horses, the person feeding it can manage without a driver from within, and assign to each horse an equal share of the draught, or such a proportion of it as may be supposed adequate to his strength. Much diminution in the expense, as well as much improvement in the mode, of farm management has thus taken place. What was the work of several months, can be performed more perfectly, and with more ease, in as many weeks; and the labour of the winter season can now be devoted to more valuable purposes, to the collecting and formation of manures, and the better preparation of the land for the reception of the seed."

8204. One of the most complete threshing machines in England has been erected at the Duke of Gloucester's farmery at Langshott Park; for the following description and drawings of which we are indebted to Mr. Andersm, an experienced agricultural engineer. This machine threshes the corn, hummels barley, winnows, sifts, and cleans corn,-grinds it into flour, cuts the straw into chaff, and grinds bones for manure; and any one of these operations can be performed without the other. The different parts of this apparatus are wholly taken from machines already in existence, but some also are original. It may be mentioned as a singular and melancholy sign of the times, that the parties who have the chief merit are afraid of giving their names to the public. The agriculturists of a future, and, we trust, no distant day will hardly believe it possible, that the destruction of threshing machines should have been popular in England in 1830. It is worthy of notice as an argument in favour of the diffusion of knowledge among the labouring classes, that, so far from threshing machines being destroyed in Scotland, they are so much in repute among the labourers of that country, that a farmer who is without
one is obliged to pay higher wages to his servants. This fact is well authenticated by a correspondent in the Examiner newspaper of February 13, 1831. (See the examination of Joseph Forster in No. 1 of The Working Man's Companion, and also in Mech. Mag., vol. xiv. p. 323.)

The mechanical part of the machinery was executed and erected chiefly by Mr. George Miller, now residing near Bagshot. Fig. 1164 is partly a section, and partly a side view; fig. 1166, is partly a cross section, and partly an end view; and fig. 1166 is partly a vertical section, and partly a vertical profile. The same letters are applied to the same parts in all the figures.

§265. Description of the machinery. (Figs. 1164, 1165, 1166.) a is an overshot water wheel 15 feet diameter, which makes from six to eight revolutions per minute according to the supply of water; on the arms of the water wheel is fixed a bevel wheel, b, of 125 cogs (seven feet four inches diameter), working into the pinion c, of 26 cogs (twenty inches diameter), on the upright shaft d; these wheels are below the ground floor, and entirely hid from the view.

On the shaft d are two driving wheels, g and j; g is a spur wheel of 119 cogs (six feet two inches diameter), driving the pinion e, of 22 cogs (fourteen inches diameter) on the shaft h, which leads to the floor above, and turns the upper millstone; f is a mitre wheel of 40 cogs (two feet diameter), working into two wheels, i and k, of the same dimensions.

On the same shaft as the mitre wheel, i, is a spur wheel, l, of 260 cogs (six feet eight inches diameter), working into the threshing machine drum pinion, m, of 20 cogs (eleven inches diameter); the spur wheel, l, also drives a wheel, n, of 20 cogs (twenty-two inches diameter), on the same axis of which is a small wheel, o, of 26 cogs (ten inches diameter), working into the wheel p, of 121 cogs (three feet four inches diameter), on the axis of the first rake or shaker; the wheel p gives motion to the intermediate wheel q, of 72 cogs (two feet diameter), which works into the second shaker wheel of the same dimensions as the first shaker wheel p.

On the spindle on which the wheel n is mounted is a small shifting pinion, r, of 17 cogs (seven inches diameter), working into the faced wheel s, on which are two rows of cogs, one of 20 and the other of 30 cogs each. On the same axis as the faced wheel s is a bevel wheel, t, of 20 cogs (eight inches diameter),
working into the wheels $u$, and $v$ of 40 cogs (sixteen inches diameter), on the lower feeding roller spindle; these two wheels are not fixed on the spindle, but revolve freely on turned parts of the shaft, and give motion to it by means of the clutch and handle, $w$. When the machine is at work the clutch is in the wheel $v$, giving to the feeding rollers the required motion; should it be necessary to stop the rollers, the handle $w$ is moved from the feeding board, and the clutch disengaged from the wheel $v$. Should the handle be moved farther from the feeding board, the clutch is thrown into the wheel $u$, and the rollers turn the reverse way.

The winnowing machine under the shakers is driven by a sheave on the drum axis, and a rope leading to a sheave on a faner spindle; to dress the grain thoroughly, it is conveyed from this machine, and passes through two winnowing machines, one placed above the other; this is effected by means of a canvas cloth, on which are strips of wood half an inch in thickness; the cloth revolves on two rollers, and is set in motion by a rope leading from a sheave on the shaft $x$ to a sheave on the upper roller spindle.

As it is absolutely necessary to have a steady and uniform motion to produce the best possible sample from a winnowing machine, and as the velocity of the threshing machine is subject to vary, from irregular feeding and other causes, the winnowing or dressing machines are set in motion by a small water-wheel, $z$, five feet diameter, on the axis of which is a bevel wheel, twenty inches in diameter, working into a pinion on an inclined shaft, $y$. On the upper end of the shaft $y$ is a bevel wheel working into a pinion, on the axis of which is another bevel wheel giving motion to the shaft $z$, which turns the faners by means of small mitre wheels.

The bone-mill and sheaf-cutting machine are driven by the mitre wheels $f$ and $k$. On the shaft $a$ is a shifting pinion, $s$, of sixteen cogs (ten inches diameter), working into the wheel $d$, of 49 cogs (two feet four inches diameter), on the axis of which is a pinion, 5, of 16 cogs (ten inches diameter), driving the wheel 6, of 40 cogs (two feet four inches diameter), in the axis of one of the lower crushers: the
upper pair of crushers are driven by the wheel 6, working into a wheel, 7, in the upper crush or spindle. The crushing rollers are set to or from each other as the nature of the work may require. When the bones are large, the upper pair of crushers only are used in passing the bones the first time through, an inclined board being placed to prevent them from falling into the lower set; this board is removed at the second time of grinding, and the bones pass through the two sets and fall into the revolving circular screen 16: any bones that will not pass through the mesh of the screen are again put into the mill. The screen is set in motion by the wheel 6, working into a pinion not shown in the drawing, and by a shaft and universal joint connecting with the axis of the screen.

On the shaft 2 is a bevel wheel, 8, of 46 cogs (twenty-one inches diameter), driving the pinion 9, of 16 cogs (nine inches diameter), on an inclined shaft leading to the floor above; on the upper end of this shaft is a bevel wheel, 10, of 52 cogs (twenty inches diameter), on the spindle of the chaff-cutting machine.

When the threshing machine only is at work, the mitre wheel 4 is thrown out of gear by the lifting screw 12; the pinion on the flour mill spindle is raised above the spur wheel 6 by the screw 13.

When the threshing machine is not at work, the mitre wheel 4 is thrown out of gear by the lifting screw 14.
The pinion 3 is kept in its place on the shaft 2 by a key; when the bone-mill is not at work, the pinion is slid along the shaft clear of the wheel 4.

There are three cogs dovetailed into the pinion 9; when the chaff-cutting machine is not at work, these cogs are removed, and the vacant part turned towards the bevel wheel 8; the person attending the chaff-machine can also stop it by the clutch and handle 15.

To stop the water-wheel, the ring and lever 18 is raised by means of a chain leading over a pulley at the upper part of the building; this raises the sluice board 17, and allows the water to escape clear of the wheel. The water which drives the small wheel 2 is also conveyed by a dash-board under it on to the large water-wheel; as this water falls above the centre of the large wheel, the loss of power sustained is not great.

The velocity of the particular parts is found by dividing the product of the number of cogs in the driving wheels of the product by the number of cogs in the driven wheels, and the quotient will be the number of revolutions made by the last moved part, for one of the first moving part. The drum will, therefore, make 49·2 revolutions for one of the water wheel; which, multiplied by 7, the medium revolutions of the water-wheel per minute, will give 341·4 revolutions of the drum per minute; as the diameter of the drum is three feet, the circumference will be 9·42 feet, which, multiplied by 341·4, will give 324 feet, the velocity of the beaters or switches on the drum per minute. By following the same rule.

The shakers will be found to make 5·42 revolutions.

The feeding rollers, quick motion 10·7 revolutions for one of the water wheel.

The upper stone of the flour mill 7·1 revolutions.

The chaff-cutting machine 26·6 revolutions.

The bone mill 30·4 revolutions.

The operative part of erecting the machine was done by a Mr. George Millar, now residing near Bagshot.

5286. A flour mill for a parish workhouse, upon a new and improved principle (figs. 1167, and 1168), has lately been erected at the Islington parish workhouse, by Weir, Oxford Street; and as it is admirably calculated for the purposes in view, and may be adopted in many similar cases, we have deemed it well worth a place in this Supplement. It consists of two pairs of stones; one pair of which can be worked separately by six men, or both together by twelve men. The moving power is a crank (fig. 1168), on the spindle of which is a large fly wheel; and beyond which is a pinion, working into a spur wheel on an upright shaft: this last wheel works into the pinions on the spindles that set the stones in motion. Either of the pinions is of course easily thrown out of gear by a lever.

There is a lower pinion pair of stones, and one governor (b), which, by means of steel yard bars (c, c) reaching to each pair of stones, regulates their motion. Each pair of stones grinds a bushel and a half of wheat an hour, and the work is performed in as perfect a manner as by any water mill whatever. There is a bolting machine worked by a crank and fly wheel, and set in motion by four men. The expense of a flour mill of the above description depends chiefly upon the size of the burr stones; these, when large, being very expensive. The improvements in this machine are the invention of Mr. Malpas, the foreman at Weir's establishment, a very intelligent mechanic, and the author of various improvements on the implements and machinery manufactured there, which do him the highest credit.
810. **Brick and tile making machines** have recently been invented by various persons. One by the Marquis of Tweeddale is in most general use, and he has recently invented a hand drain-tile making machine, which was honoured with a premium in 1843. Messrs. Ramsone have also brought forward a new machine for making tiles and bricks, which received a silver medal at the meeting of the English Agricultural Society at Derby in 1843.

811-790. A **hummelling machine**, of a simple, but very efficient construction, is described in *Trans. H. S.*, vol. x. p. 331. "The machine consists of a deal box (fig. 1170.) in the form of a truncated square pyramid, 30 inches on the side at the base, 20 inches at the smaller end, and 48 inches in length. In the interior of the box, the two lower angles are filled up with wood, so as to form the half of an interior conical surface; while the two upper angles are left void, except that their surface is thickest studded with iron spikes, driven into the wood of the box. An iron axle, or shaft, a b, as seen in the longitudinal section (fig. 1170.), passes through it, in the line of the axis of the conical surface, and is supported on bearings at each end, formed in the bars crossing the ends of the box. The shaft is armed with two rows of blunt iron beaters, seven in each row, all lying in one plane; the beaters on the one side of the shaft being placed alternate with those of the other. When the hummeller is in the working position, the opening d, in the smaller end, is brought under the corn spout of the threshing-mill fanners, supported on the foot e, to bring the axis to the horizontal line. The vertical lines bounding the space f, represent a transverse section of the outline, of the fanners, the prolongation b c, of the shaft passing through it, and attached to the principal shaft by a coupling box at b. The journal at c, is supported on a bearing formed either on the fanners or a separate framework.

The pulley g, giving motion to the beaters, is driven by a strap from the fan-shaft, or from such other motion as may be found convenient, giving the beaters a velocity of about 400 revolutions per minute.

The grain received from the spout of the fanners is violently agitated in its progress among the revolving beaters, and, the lower side of the case having a considerable inclination, the grain is advanced during the process towards the lower orifice, through which it is ultimately discharged; that opening is made capable of regulation by means of the slider h, which serves, at the same time, others in the grain within worked by two men, or by horse or engine power, at various prices, from 10l. to 36l. When made entirely of iron, they are comparatively of little use. The manufacturer of these machines is chiefly Dean of Birmingham. (Johnson's *Agr. Imp.* for 1848, p. 29.)

**Chap. III. — Edifices used in Agriculture.** (p. 442.)

823—2511. **Edifices in use in agriculture.** In the *Encyclopedia of Cottage, Farm, and Villa Architecture*, we have gone into this subject in greater detail than could with propriety have been done in a
work embracing so extended a view of agriculture as the present volume. In that work, including the Supplement to it published in 1842, we have not only given a great variety of the best plans for farmyards, or farm-houses, which have been executed in Britain within these few years; but we have given plans, sections, and specifications of all the component buildings of a farm-yard, and of their fittings up, fixtures, and furniture.

2812. Stables in Sweden. Having entered on this subject at length in our Encyclopædia of Cottage, Farm, and Villa Architecture, and there given numerous plans, accompanied by descriptions, specifications, estimates, and critical remarks, we shall not here repeat any thing which has appeared in that work. As the dwellings are the ornament of the improvements, so is the method of erecting the buildings upon which the floor is laid, should rest upon stone and lime building, raised two feet from the ground, close to the barn wall; and the mortar and stones must be packed close to the upper edge of the sleepers, up to the deals of the floor. According to the width of the barn, the floor will be supported on one or two more stones, or to a vermin; and which will support the middle of the floor. By this contrivance, the space from the floor to the ground is made too deep to permit any small animal standing on its hind legs and gnawing the floor, while dogs or cats cannot easily pass under it. (Book of the Farm, vol. i. p. 118.)

2816. Barn floors, to be proof against the ascent of rats from beneath, should be formed of wood, or covered over with asphalt, which is to be press’d down to be perfect; and the kind of vermin, which must be be apt to appear,-the vermin upon which the floor is laid, should rest upon stone and lime building, raised two feet from the ground, close to the barn wall; and the mortar and stones must be packed close to the upper edge of the sleepers, up to the deals of the floor. According to the width of the barn, the floor will be supported on one or two more stones, or to a vermin; and which will support the middle of the floor. By this contrivance, the space from the floor to the ground is made too deep to permit any small animal standing on its hind legs and gnawing the floor, while dogs or cats cannot easily pass under it. (Book of the Farm, vol. i. p. 118.)

2817. Houses are little used in Scotland, notwithstanding the mildness of the climate compared with that of England. In making meadow or natural hay, they have lately been found of great advantage in Scotland; where meadow hay of the same degree of dryness that would rot if put into a rick, will keep perfectly if put in a hay shed. This article of hay is cultivated for the purpose of supplying the local and the hay being put in loosely. Were landlords sufficiently alive to the value of the hay barn, one would be built on every steading in districts where meadow hay is made. (Trans. H. S., vol. iv. p. 697.)

2818. Labourers' cottages. Having entered on this subject at length in our Encyclopædia of Cottage, Farm, and Villa Architecture, and there given numerous plans, accompanied by descriptions, specifications, estimates, and critical remarks, we shall not here repeat any thing which has appeared in that work. As the dwellings are the ornament of the improvements, so is the method of erecting the buildings upon which the floor is laid, should rest upon stone and lime building, raised two feet from the ground, close to the barn wall; and the mortar and stones must be packed close to the upper edge of the sleepers, up to the deals of the floor. According to the width of the barn, the floor will be supported on one or two more stones, or to a vermin; and which will support the middle of the floor. By this contrivance, the space from the floor to the ground is made too deep to permit any small animal standing on its hind legs and gnawing the floor, while dogs or cats cannot easily pass under it. (Book of the Farm, vol. i. p. 118.)

2819. The beaut ideal of an English labourer's cottage. The leading feature in the exterior of a labourer's cottage should be a picturesque simplicity, which is a sort of medium between superfluous decoration and unmeaning plainness. This appears to be the only character of which a cottage is susceptible; and nature, by her own unaided work, inflicts on it a decoration bedecked with costly fantastic ornaments, which are evidently unsuited to the simple unrehearsed beauties of humble life. But a picturesque simplicity is seldom the perversing character of modern ornamentation; frolics and caprices are intermixed with tawdry decoration; and in the public, and in the monastic style, with elaborate painted windows, crosses, and pinnacles; nay, instances have occurred where the two styles have been united in the ornaments of a cottage dwelling. It cannot be denied, that a picturesque effect is produced by this mode of embellishment; all I contend for is, that such ornaments are altogether unsuited to a dwelling of the lowest order. Should it be objected, that, if we reject this mode of decoration, we must recur to ruin and decay to produce a picturesque effect; I answer, that as much of this effect as we may require to produce may be obtained, I think, by irregularity. In fact, the beauty of cottage architecture is, I believe, to be obtained by irregularity. As to the question whether the cottages should be made in a picturesque style, and have all the embellishments in the cottages, which we find in the grand houses, I am not for it, that all we require to produce what I understand by picturesque simplicity. Though I am an advocate for simplicity, however, in cottage architecture, I would in some measure sacrifice even simplicity to the picturesque; because the beauty of a neighbourhood frequently depends upon the style of the surrounding buildings. They should, in general, be ornamented in a manner so placed and associated with surrounding objects, that they present the most striking features in the landscape; and the effect of particular scenes is not unfrequently produced by the forms and situations of the cottages. Hence, a picturesque exterior is one of the chief requisites in an ornamental cottage; but it should be a simple pleasing style of picturesque, which does not interfere with internal comfort and convenience; produced by slight irregularity of form, and by obtrusive and appropriate ornaments. I am not at all disposed to sacrifice internal comfort to outward effect. I think a picturesque cottage may be, and should be, with a comfortable interior, and I now proceed to give the description of a cottage in which I shall endeavour to exemplify the union above alluded to. (Quart. Jour. Agric, vol. iii. p. 956.)

2820. Site of the cottage. As the comfort of the inmates and the general effect of a building depend mainly on the situation, the first thing a cottage is the site of its location. A general rule, for the site of a cottage, is that it should be properly supplied with water; be dry, airy, and sheltered; and admit of a sufficient allotment of garden ground adjoining the house. And I am an advocate for rather a scattered village, because, among other advantages, it affords an opportunity of erecting the cottages in proper situations. A damp situation is the principal thing to be avoided. It is a nuisance in all cases; but especially to a labouring man, who cannot afford to spend any thing in draughting, or much in fuel; whose health is his only source of wealth, and to whom it is necessary, both for repose, that he should have a dry house; and for the preservation of fuel, that he should have it in a dry house. The air of the open country is so peculiarly invigorating, that the health of most country folk is much greater than that of the inhabitants of towns. The cottage, that be best adapted to a comfortable interior, and I now proceed to give the description of a cottage in which I shall endeavour to exemplify the union above alluded to. (Quart. Jour. Agric, vol. iii. p. 956.)

2821. Style of the cottage. Having fixed upon the site of the cottage, the next thing to be considered is, in what style is the building to be erected; for even a cottage, I think, should present some appearance of architectural style. I have already contended that the Gothic is inappropriate to a dwelling of...
this description, and a building in the Grecian or Roman style, upon so small a scale as a cottage, must be plain and formal, and deficient in picturesque effect, unless it be an elegant and costly edifice. There remains, therefore, only what is called the old English style, which is, I think, the proper style of architecture for England, judged by the great irregularity and variety of frame and roof of the cottages of all dimensions. Its ornaments may be adapted to the smallest dwellings; the irregularity it allows in the exterior, may be made conducive to internal convenience; and it has this peculiar advantage, that the greater part of the external decoration may be completed without the use of expensive ornamental materials. The desire for it is often indicated by the tall chimneys; by the high pointed gables, with, perhaps, small pinnacles at the angles; by the mulioned windows and the labels over them; by a projecting porch of one or two stories; and by the string-course which gives a touch of the original kind to so many of our buildings. Moreover, in small houses, the whole of the upper story might be formed of a wooden framework, filled in with brick or plaster. This wooden framework would project beyond the wall which supported it, and produce a pleasing effect of light and shade, and a variety of ornament might be given by the form of the frame itself, without the expense of materials used in the construction of it. And it is not improbable, that the plaster, with which the interstices of the frame are filled up, in these half timber houses might be introduced of a kind of wooden oriel window, which is one of the most striking ornaments in many old cottages. The gables over such a building might have handsome semi-oval windows at the points. These pinnacles, if small and in good proportion, would be in keeping with a mode of building which admits of a great variety of embellishment, and is well suited to a district where stone and other substantial materials are scarce and expensive. As it possesses these recommendations, we shall adopt the old English style for our purpose, and suppose the cottage erected on a dry, airy site, well protected from the prevailing winds, and surrounded by its garden, orchard, and out-buildings. It would, of course, present one regular front. This we shall divide into two equal parts by a porch; the whole story of the porch being the lower part. The upper part, above, a neat mulioned window of two lights, with its proper label; and over this a low gable terminating in a simple ornament. On each side of the porch might be a mulioned window of three lights, placed immediately within the house; and in the stories below these windows would be plain, as the windows of the rooms in the chamber floor would be most conveniently placed in the gables at the ends of the house. In the centre of the roof, behind the porch, would be the stack of chimneys, which should be tall, and rather the handomest member of the building. It is the most important part of the whole, and depends mainly on it for its beauty. These starchy, cylindrical pipes of the stack of chimneys. This front would afford an example of what I understand by picturesque simplicity. There would be a certain symmetry and unity about it; it would present no superfluous ornament, which is still it might be thought, a highly commendable feature. It might contain many internal conveniences which are not always found in buildings of more pretension; and it would possess enough of the picturesque character to make it harmonise with the surrounding scenery.

§822. Interior accommodation.

Such then, would be the exterior of the cottage: what are the accommodations it should contain within? A comfortable labourer's dwelling should, in my opinion, consist of an entrance porch, kitchen, washtub, pantry, and small cellar, a parlour or spare sitting-room, and a series of two or more double bed-rooms, and a parlor for the accommodation of a family, even in humble life; and, as we are attempting to describe the house ideal of a cottage, we must suppose it to contain all these conveniences, which we proceed to describe in their order. A porch, besides being an important part of the external appearance of a cottage, is necessary for the convenience of the cottagers, who are sometimes driven by the weather to shelter the entrance from wind and rain, and thus assisting to warm the interior. A cottage should be of small dimensions, the floor on a level with the rooms within, and raised a step or two above the surrounding surface. It should be panelled and coved, and should form a kind of square entrance-hall, which, though small, might often sit at work in fine weather. Over the seats might be shelves, on which small tools might be put away, and seeds, onions, &c. placed to dry. There should, of course, be a scarpers at the steps, and a man with the entrance.

§823. Kitchen.

From the porch you should pass through a small lobby to the kitchen, or common sitting-room of the cottage, which should be a sufficiently spacious, light, and airy apartment. The object of the lobby is, that there may be two doors between the living-room and the outer air, which in summer are always left open in the highest degree, and that in winter a current of air may be admitted to cool the air in the house, and suffer the cottage to be dried by natural ventilation. The windows of the kitchen should be high, to let in the greatest possible quantity of light, which should be furnished with a sufficient opening for the admission of fuel. There should be, as many as properly can be ordered, at least three in the interior of old cottages, which ought to be avoided when new ones are erected. I allude to the lowness of the rooms and doorways, damp floors, and smoky chimneys. If we were to judge of the people by the houses they inhabit, and the manner in which they spend their time, both the old cottages and the former inhabitants of them would have been "pride," to have been absolutely a race of dwarfs. For, if you would avoid a broken head, you must actually creep through the doorways of ordinary cottages; and, after escaping the perils of the doorway, a man of good stature can seldom stand upright in the house without being partly crimped by the low beams, the narrow space between the wall and the ceiling, the low frames of the doors and windows.

Another common defect in cottages, is the dampness of the ground-floor. In the case of old cottages, the ground-floor is usually much below the level of the surrounding surface, and you generally descend into the house, and are met with the lower apartment, which is so sufficiently described. The consequence is, that, in many situations, the cottages are damp and uncomfortable for five or six months in the year; indeed, I know several cottages in which springs of water regularly break through the kitchen floors during the winter season. Another deficiency is, that the general rule of every description of this dwelling should be that the house should be eighteen inches or more above the surface, and that the earth on the outside should be the same distance below the level of the floor. Under every brick or stone floor there should be a substratum of broken stones, or flints, the nature of the surface for the earth to receive it on, and the flints may be necessary to have this substratum two or three feet deep, with drains and air passages through it; and the earth should have a good slope on the walls on every side, so that the water from the roof can escape rapidly, and not sink into the foundations. Another point of great general importance in cottages, which I have had occasion to mention, is that the floor of the upper story should be a foot above every one; but it is especially so to a cottage, because, over and above the dirt and discomfort occasioned by the smoke, half the fuel is wasted in a fireplace which has not a proper draught. This nuisance in cottages generally arises from the impossibility of the fire being large enough. There are no fires in cottages on the outside, and the air currents from the atmosphere occasioned by the bad positions of the doors and windows, which seldom fit close. From whatever cause it arises, a smoky chimney is a prevailing misery in labourers' dwellings, which a judicious builder may get entirely out of the way by sitting upon this subject in the Essay on Encyclopaedia of Cottage, Farm, and Villa Architecture. After this digression, let us return to the cottage kitchen. This is the common sitting-room of the family, in which most of the household occupations are to be performed, it should be a light warm apartment, of a good size. We will suppose it sixteen feet square, and eight feet high, having a window in the east and one in the west. It would
thus have the benefit of the morning and midday sun; an important advantage to a cottager, in whose domestic expenditure coals and candles are considerable articles. Stone is, I believe, the best material for the floor, as being most durable and easily kept clean, and in these respects greatly to be preferred to brick. Boards, besides that they are liable to occasion accidents by fire, cost less; but it is absolutely necessary that they should be kept scrupulously clean, and the room in a clean, neat, and airy state, if not to be loathed and shunned by both sexes of the inhabitants. Of course the walls and ceiling should be neatly plastered and whitewashed, and there should be a proper skirting-board round the room, and attached inside shutters to the windows. The fireplace should be so situated as to be well lighted by the windows; and the chimney, thus being the best, should be so placed as to afford the heat produced, confined to one place; and, should this place be near the centre of the building, the mass of raw masonry must have the effect of raising the general temperature of all the apartments of the cottage, as the inhabitants were not usually met with; but, where wood is the principal fuel of the peasanzy (as it is in the district from which I write), I would indulge their prejudice in favour of an open chimney, and will suppose one in the cottage kitchen, with the mouth of the even on the side of the back wall, and on the other a small copper set in an arch, having a free tube through the arch by which the steam might escape up the chimney. It would be tedious to describe minutely the various articles of useful and ornamental furniture found in the kitchen of a thriving cottager; indeed, to those unacquainted with rural life it would be difficult to convey an idea of the multitudes of collection often displayed in this kind of house. With my labourer's wife is sometimes as fond of knock-knacks, and as proud of displaying her various stores, as the richest lady in the land. The peasanzy have, in fact, many of the prevailing tastes of their superiors in wealth and refinement, and love to ornament their cottage houses with their toasts, and odd ornaments, as often as they can collect them, and as often as they can afford them; as much crowded with useful and ornamental furniture as a modern drawing-room. The mantel-shelf displays a range of vases, cases, and painted busts of the favourite heroes of past and present times, mixed with some foliage, or other ornament. The glass cases, for displaying utensils, old china, and old copper, are particularly pleasant, and the people often collect an entire day's produce of exotics, thriving surprisingly, some of them in spoutless tasses and other discarded vessels; and on the window seat, or a shelf near a heap of books; the bide, in a neat cover, reverently placed apart from the rest. Even the ceiling is generally decorated with that desire, or that want, which is frequently arranged with such conspicuous articles will not, perhaps, bear a close examination; and are, in fact, useless; though "wisely kept for show: but she contrives to hide defects, and the shelves often exhibit specimens of old glass and china, which a collector of such rarities might covet. They are, more probably, the only ornaments the interior of the cottage of a plain labourer who happens to have a tidy wife; and I have often been much pleased at the air of decent comfort, and at the decorated effect produced by the miscellaneous collection seen in a room of this description.

236. Furniture of the kitchen. Among the more prominent articles of furniture in a thriving labourer's kitchen, the clock, I think, takes precedence of the rest in the owner's estimation, and its well-polished case generally is a conspicuous object. Next to this we may rank the best dining-table, often one of those interesting old oak tables, and four, or six, beech or birch-bough chairs, with its best teatable, turned up, with its pillar and claw, in a corner; and the dough trough with its clean white cover, would next attract attention. To these we may add the great arm-chair, with a patchwork cushion in the bottom, for the manifestations of which he is emphatically said, a seat of his dignity, surmounted by his wife and children, forming, in many cases, a happy, interesting group: the wife and enter girls at work, perhaps, while one of the boys is standing by the father, reading, or repeating what he has learnt at school during the day. I hope there are many such evening gatherings still in our cottages and farms of the noble art of polite conversation, the simple, but pleasant piece of furniture which I should wish to see in every cottage; I mean, a shelf of useful and instructive books. You seldom enter a cottage without finding some books; indeed, as far as my observation extends, I shall say that a taste for reading is becoming more general. It is to be strongly urged, as a source of instruction and enjoyment, which has a tendency to improve the morals and better the condition of the peasanzy. What a wide field of knowledge and enjoyment is cut off from the labourer who is unable to read, or who has no taste for reading! Half the leisure of such a person must be spent in drudgery indolence, or in the debasing scenes of the ale-house, to which he is almost driven in self-defence, to relieve the tediousness and oppressive vacancy of his mind: the want of this resource and comfort is severely felt by the uneducated labourer in times of sickening and old age, when a long life of productive life is not necessary. There are few of the rising generation entirely without education. The stores of knowledge will therefore soon be opened to all the labouring classes, and they should be encouraged to use them to their own advantage, by having their attention directed to useful and improving books. A little learning, if you would speak in a direct thing."
8225. A small larder or pantry, having a window in the outer wall, should communicate with the kitchen or wash-house. This is a necessary convenience not often found in labourers' dwellings, in which the provisions are generally kept in nasty close cupboards, or on shelves in the living-room, where the bread, bread dough and various parts of imported food are kept. A better place, even the beer or cider barrel is kept in the warm kitchen, and in such a situation the liquor, of course, soon becomes sour and unfit to drink. No cottage, therefore, should be without a cool air of the yard. If the space is not already divided, it might be with little or no addition to the cost of building. As I am describing the bead ideal of a cottage, the owner or occupier might keep a cow, I will, in the present case, suppose the larder of a sufficient size to contain both the milk and provisions. We can scarcely expect a distinct place for each in a labourer's cottage, and it would be a pity to waste the spaces for the milk and provisions. We should have shelves for the small cheeses, which a managing woman would of course make during the summer season, even from her single cow.

8226. Cellar. If the floor of the larder were sunk the depth of a yard below the surface, the beer might also be kept in it; but a cottage would not be quite complete without a small cellar, to contain the beer, and the potatoes and other roots. A cottage with hail would grow a large supply of potatoes and other roots, for his cow and pigs; and it would save a great deal of time, and prevent waste, to have the roots in a separate place of cultivation. There might be separate shelves for potatoes, as well as other needful shelves for the small cheeses, which a managing woman would of course make during the summer season, even from her single cow.

8227. Color washing. I am not quite sure that I should add this, as the practice is not extensively followed in this country. But, when we consider the circumstances of these cottages, and the amount of work necessary, we shall feel that it must be considered as a duty that must be performed. The cottager, therefore, should be taught the practice of colour washing, and the necessity of cleanliness. He should be made to understand that it is not a matter of difficulty, but of cleanliness. If the cottage is kept clean, there will be no need of colour washing.
ENCYCLOPEDIA OF AGRICULTURE.

Supplement.

8231. General remarks on the interior. Having described the interior of the cottage, let me pause and inquire, whether there is any thing in the description which can be justly considered superfluous, and not absolutely necessary for the comfort of the occupier. And accommodation for the necessity of any thing to which a reasonable objection can be offered unless it be the parlour. The idea of a cottage parlour may lead some to exclaim, "The man must be a fool! Who is to do the work, if labourers are to be fine folks, and sit in parlours? My friends have never the idea that there are any workmen of this sort, and we will have all works, and perhaps you will no object to it. Call it the spare room, for instance; a place to be used for all sorts of purposes: for such it would be, in fact. Unless when the wife was confined, or any of the family happened to be recovering from illness, I will answer that the house, are used as a parlour three or four times a week, and that it became a sort of an occasional labourer in the parish. In rainy weather, it would be degraded into a drying-room, and be filled with wet linen; and the floor would often be found half-covered with umbos and seeds laid there to dry the roots of vegetable for which such a room is the occasion of it, even though it may be called a parlour? If such an apartment would have a tendency to give the pea-santry fine notions, I should be the last to recommend it. For I hate fine people of all sorts, and fine poor people above all others, because they have not an excuse for finery. But when an occasion is presented to their inhabitants improved, and I know, from painful observation, that our cottages stand in need of improvement. They are, in fact, behind the times; and while the houses of every other class of society have been gradually increasing in comfort and convenience, the dwellings of the labourers are not thus improved but in a few years. Many improvements and conveniences in cottages have been suggested by others, which I forbear to notice; for this reason, that while such conveniences are unattainable by persons of small independent proerty, it is in vain to expect that they will be provided for cottagers. My object has, therefore, been to discuss improvements in cottages, and to suggest practical improvements which are likely to be effected; and I hope that there is nothing in the foregoing description which can be considered impracticable.

8232. Appendages to a labourer's cottage. I now come to speak of the external appendages to a complete labourer's dwelling, including the yard and out-buildings, the garden, orchard, and allotment of land. To account for some of the out-buildings which will be mentioned in the following description, I must remind the reader that the term of a cottage is a term of speaking of a cottage as a whole, and that, besides a quarter or half an acre of land, for spade husbandry, (the quantity should be proportioned to the spare time of the labourer, and the quantity of manure he can collect,) he would also be the occupier of about three acres of pasture. I am of opinion that it would be of material effect upon the general comfort of the occupier in a certain number of cottages, with land attached to them, in every parish, to act as a sort of stimulus to industry and frugality. Formerly the small farms presented this stimulus. The industrious, saving cottager had the original enclosure, and a good proportion above his own tillage, and they kept him in his 50th year.

Now this is all very well; the principal sum is secure, and a certain 21. a year is a desirable addition to a labourer's income. But it would take nearly his whole life to save up 50L., and half that sum would produce a much greater income, and much improve his condition, if employed in some sort of business. In short, though the savings banks have been of great benefit to the working classes, the small income produced by a sum of money placed there does not afford a sufficient stimulus to frugality. The interest upon their savings can add little to the comforts of the depositors; and, as to having any sum of money available, that is all they get from it; they must thus then support them; and though they might be induced to save, if by saving, they could materially improve their condition, we must not expect them to save for the relief of the parish. But let us suppose a man to have saved only 25L., and to have an opportunity of taking a cottage, with land, of the sort I speak of for 12L. a year. He would look to it as a cow, a pair of horses, a couple of pigs, some poultry, perhaps, and a hive or two of bees; and, if he had tolerably good luck, and were a good manager, he would be able to purchase his 25L. at 5 per cent. interest, and he then had 25L. in the bank, and nearly 5L. a year in interest. The great improvement in his condition would also be apparent to all around him, and would act as a general spur upon the carefulness and industry of his neighbours. Money in the savings bank would not produce this consequence, because its effects are less apparent; in short, its effects are imperishable. Things may be said in this building, to a labourer's family, of keeping a cow. But, besides being prizes to excite the diligence and reward the good conduct of the labourers, a few cottages, with land attached, would be a general convenience to the villagers, as a means of supplying them with milk, a luxury which, in my neighbourhood, is very little known. The country, they are worse off than townpeople in this respect, as they cannot get it for money, unless on some particular occasion. The cause of this inconvenience is the large farms, and the want of cottager's cows. A rich farmer is, of course, above selling milk, and there is no one else to sell it, unless there was a great rise of it. They would then be more in demand, and more convenient, and more profitable. I offering these few reasons for the opinion I have ventured to advance, that in every village a few cottages with land to keep cows would be desirable on many accounts. I do not say that every cottage should keep a cow, but a cow would be a great deal better than nothing; it would be much better, and the cottage would be more, and it would be more convenient to keep a cow, and the cottage would be more; it would be more convenient to have a cow, and the cottage would be more convenient. It would be more convenient to have a cow, and the cottage would be more convenient.
SUPPLEMENT. SCIENCE AND ART OF AGRICULTURE.

8235. _The cow-house and piggery_ should be near the dung-pit, that the drains from both may be laid into it at little expense, and to save the cottager's time in cleaning out the cow-stall, &c. The cowhouse need only contain one roomy stall and a calf-pen, with a small loft over both for the hay brought in for use. This stall should be divided in two, so that the store-pig, which a good manager would never be without, might be separated from the fattening pig.

8236. _If a poultry-house should be required_, I would place it either over or adjoining to the cowhouse, for I do not think it would answer for this purpose, unless in situations where there is a ready sale for eggs and chickens, and where poultry can be kept without being a nuisance to the owner and his neighbours. In a widely scattered village this may sometime be the case, but in the houses are near together, the cottager's fowls are continual source of dispute and annoyance. They are ill-fed at home, and cannot stray anywhere in search of food without trespassing upon a neighbour's ground, where, in the absence of the family at work, they may devour or destroy the apples of the garden. Where the houses are scattered, and a cottager has land of his own, he might have a run for his fowls, and could let them run to the woods, but it would answer his purpose to keep a few fowls; that is, if he can keep them out of his garden, but otherwise it would not work. If water is near, ducks would be most profitable to a labourer, and more easily managed than hens.

8237. _Pigpen_. I do not recollect any other out-building actually necessary for the cottager's convenience, unless it be the privy, which might be either in the yard or in the garden, and if desired, I see no objection to one in each place. But it is useless to talk of a separate convenience of this kind for males and females. I believe that wherever a family live, a good term for a new-built cottage should be the privy; but in my own neighbourhood, where I have out of sixteen dwellings near me, six only have the convenience alluded to, and of the six conveniences have been erected in or near the garden, the privy must be driven away, at least, as a matter of convenience to the cottagers; and I particularly recommend the subject to the attention of cottage owners.

8238. _General observations on exteriors_. As the fence of the yard and the outbuildings would add something to the value of the garden, it is not without objection that I suppose and recommend only the least expensive out-buildings, such as the cottagers, with trifling assistance, would very readily erect themselves. The cowhouse would be the chief expense, and that would be little better than a common shed, walled up with anything on three sides, and open to the south. But I would have a stone wall at least well at night. For the blackberries, which would probably cost the owner at least a day's work, when his cow or pig happened to get astray. I do not mention any place for pigeons in the yard, because a cottager could not keep them without constantly treading upon their flocks. On the other hand, if pigeons do not increase piggery they are very troublesome to the farmer at certain times in the door. Dovecots are now much less frequently seen in farmyards than they were formerly, at least in the corn-growing districts; and if the farmers can no longer keep pigeons, of course the labourers must not. Where the cottage stands near a common, or another labourer's property is, a particular case, a piece of land is left to each farmer as a desirable kind of stock, because, after a certain age, they almost take care of themselves. They would require to be secured at night; and, if the cottager keeps geese, he must add a house for them to his outbuildings in the yard.

8239. _The garden_. If well managed, is commonly the most striking feature about a labourer's dwelling, and there are many reasons why it should adjoin the house. In the present case we will suppose the cottage to be surrounded by a garden, and the cottager to have one approach nearly a part of the garden which divides the house from the road and this part of it would devote chiefly to flowers and shrubs. I would train some ornamental climbing plants against the walls of the house, and a vine or pear-trees, if there were proper situations for them, where the fruit would ripen in most cases. I observe, however, that, excepting blackberries, which do not even thrive much against the walls of cottages; there are a great number of fruits and vegetables, which can thrive, though not so luxuriantly, by a fence, if they are cared for; I mean the blackberries, which are not often seen nor cultivated, and the currants, which are of the greatest value in fruiting, and which are kept alive by an occasional ripening of their fruits. The stone wall, and a little care, would suffice for these, but the best way would be a small vinery, and to train the vines up it. But even then the gentle-rake, and the blackberry, perhaps, will not come to perfection.

8240. _Orchard_. Besides the garden, it is desirable that every cottage with land should have a small orchard attached to it, especially in the elder countries; and, in extensive allotments of land, there are generally rough places, which, being of little value for any other purpose, might be converted into small orchards. In his description. I would plant the orchard immediately behind the garden, and contiguous to the house, that it may be easily overlooked by the owner; I would also rear a good hedge round it to keep out intruders, for young cottagers are as fond of sour apples as the little children are of sour biscuits, and they are not at all particular about the orchard or the garden of small fruit, they will do a great deal of mischief, if not guarded against. As it is scarcely possible to have too much fruit, and a peasant's orchard is not likely to be large, I would plant some fruit-trees in the hedges of the garden, and others Damsons and a few Quinces, and if the fish can be kept still farther from the house, a delicate pear-tree with some large fine pears, and perhaps an apple-tree, and a few plum-trees, and a sweet mulberry, and a bitter one, and a few peaches. But it is very well in the hedgerow, and would be very ornamental. I think a orchard should produce apples, pears, and plums of various kinds, but chiefly apples. Fruit will sell everywhere; and it is desirable that a cottager should have as many ways as possible of making a little money from it. But fruit-trees, and a general fruit-house, would do this at a very trifling expense, by having a small cottage nursery, in which his gardener might graft and rear fruit-trees of good kinds, to transplant, when fit, into the cottagers' gardens and orchards. Many labourers are fond of grafting; and, were the ground round the orchard free and not kept. I wonder our landowners do not see the advantages of planting their cottage grounds with fruit-trees by which they would increase the value of them, and place in the hands of the tenant the means of paying the rent. They are but a common thing, and greatly increase the marketable value of our villages, by surrounding the houses with fruit-trees, which are the most interesting of all fruits. What can be more beautiful than a handsome apple tree covered with rose blossoms in the spring, or loaded with golden fruit in autumn? It is picturesque even in winter, when its rugged branches, without the protection of its leaves, are exposed to view. How lovely a village with many small orchards about it is generally a pretty village.
**Potato-ground.** The next thing to be spoken of is the allotment for potatoes, &c., without which no cottage would, in these days, be thought complete. But, of course, this allotment would be much smaller in the case of a cottager keeping a cow, than in that of a labourer with only a garden to attend to. The cowkeeper would have a cow, and he would have to cultivate a little odd piece of ground, in order that he &c., should therefore be smaller than that of another labourer, because the man will not have much leisure, and the wife will have less, as she will have the produce of the cow to manage, in addition to the ordinary housework. If the cowkeeper had the advantage of the cow, the case would be altered, and he would require as large an allotment as other labourers. He would probably have on his ground a different plan from that followed by ordinary cottagers. He would not have space for a plot of corn, and it would answer his purpose better to grow cabbages, Swedish turnips, mangolds, &c., in the corners, and all the valuable apparatus for the cow, as well as the potato crop; indeed, a man who has a cow and pigs should consider their wants in his gardening almost as much as he does those of his family, and his pigs should nearly live on vegetables during the summer. We conclude therefore that a few oblong pieces of ground should occupy for the use of his cow. This should be about three acres, divided into two enclosures. I believe three acres of fair grass land are generally considered the quantity required to summer and winter a cow; but, if a less quantity would be sufficient, the course of his land would not desire much alteration. He had better have rather too much land than too little, as the profit of a cow depends in a great measure on its being well fed. He would probably now his fields for hay alternately, as he would not be able to manure very freely. He must, however, manure a portion of his grass land every year. In addition to this, I would have all buildings, &c., put up as near as is practicable to the ground mentioned, so that he may be enabled to do decent comfort of a family. My aim has also been to speak of practical improvements; and to show how the domestic accommodations of the peasantry may be increased at a moderate expense. There are many desirable improvements and beauties suggested by writers on cottage architecture, which I have for the most part omitted, for this reason, because costly, and I hope it is not unreasonably supposed, and it is useless to recommend luxuries for labourers' dwellings, which are not found in the houses of wealthy farmers and tradesmen, and even in those of the smaller gentry. Our peasantry, however, have not the means for luxuries and improvements. They can only get the benefits above all, sufficiently roomy dwellings, in which their families may be conveniently accommodated, without violating the common decency of life. If they had houses of this description, they would have cared for and managed them well; and so, without uneconomic luxuries, and with the consequent fast advancing when the improvement which has taken place in the habitations of all classes above them will be extended to labourers' cottages.

—864. **Asphalt,** as the upper layer of the floors of cottages, effectually prevents the rising of damp; a winter season, when the carts require to be loaded on the evening preceding the market-day; as it can be done before yoking (putting the horses in), and without moving the carts from under their cover, by
means of the trap-door in the centre passage of the granary: which passage must at all times be kept clear from grain. In the straw-house, a trap-door is placed over the straw-rack; and, when the lower part of the house is packed full, this trap-door can be shot, and the straw carried along the upper floor to the straw-chambers over the stable and feeding-byre. These apartments will contain the straw of two ricks, which will enable the farmer to keep different kinds of straw under cover, and in separate divisions. A door is placed opposite the passage which extends along the centre of the straw-yard for taking out straw for the cattle-sheds, cow-byres, &c., if at any time required; but in general these are supplied from the low straw-house. The threshing-machine is one of six horse-power, and is impelled by horses; but where water can be had, it is a great improvement, as the men may be employed threshing, while the horses are resting; this is advantageous in a still greater degree at certain times, when the field operations exhaust all the horse power.

The circular byre (q), which will contain ten head of cattle, is by far the most commodious and convenient arrangement; and, for a farm double this extent, the same form may be introduced, with equal advantage. But the stalls wholly round the circle where the sheds are. The figure of the stables, being broad behind, gives more space for the cattle when lying down; and, as a greater quantity of litter is requisite, more manure, of course, will be made: at the same time it admits from behind a more constant supply of fresh air, and has also the advantage of one large ventilator in the centre of the circle serving the whole. The ten head of cattle are put up in double stalls in pairs; they are bound up, one on each side of the partition, which is made high enough to prevent the horned cattle from touching one another; at the same time keeping the heads of each pair at such a distance apart, as to prevent them from injuring each other, or eating each other's turnips. The bends, or cow-cotes, are fixed to upright iron rods about three quarters of an inch in diameter, which are screwed together through the partition. The lower part of the windows in the back wall of the byre are filled with louver-boarding, which can be opened to any degree for admitting air, or shut altogether at pleasure. The feeding-ports, or openings which surround the feeding-chambers, have small doors hung with pulleys, lines, and weights, similar to those of a common window, which, by moving upwards, do not interfere with, or occupy, any part of the chamber. The wall at the heads of the cattle surrounding the feeding-chamber is built to the full height of the joists; which keeps the turnip barley out of the view of the cattle, and does not disturb the one.
division of them, while the man is in the act of feeding the other. This is important, as the quieter cattle are kept the better, quieter being, no doubt, essential to quick fattening.

8249. A commodious straw-chamber is obtained over the byre, in a connected range with the straw or hay chamber over the stable: the roof, which is of considerable width, has the double purpose of covering the feeding byre, and of containing a very large quantity of straw immediately over it. Racks are placed over the several stalls, which are filled from the straw-chamber above. By this arrangement, the cattle have in their power to eat straw and turnips alternately, if inclined. The access to the straw-chambers over the byre and stables is by a stair, which is common to both; and upon the plate (first landing-place) of this stair is placed a door, which divides the stable from the feeding byre; the upper flight of the stair is understood to be a hanging one, having a useful space under it for holding the byre implements. By the whole arrangement much labour in feeding and attending the cattle will be saved.

8250. The stabling (c, f) consists of ten stalls, three of which are separated from the general farm stable, but are so situated as to admit of the racks being supplied from the general straw or hay chamber over the common farm stable. They are understood to have two sets of racks; the upper are for hay or straw, and the under one for grass.

8251. The turnip-shed (i), adjoining the feeding byre, is also conveniently situated for supplying the cattle in the straw-yard; and, as it is not required for turnips in summer, it may be used for and serve the double purpose of a turnip-house and a grass house.

8252. Ventilators. The cow byres have ventilators placed over each line of heads; these cross the ridge, and are formed of lead of a triangular figure; the sill piece being overlapped by the sides far enough to prevent the rain from getting in. (See c in fig. 1173.)

8253. The calf-house and ward, and the cow byres (c, d), which fall under the class of offices more immediately connected with the farm house, have doors facing the kitchen-court, which makes the access to them convenient and clean. The opposite doors are used for driving out the cattle, and for wheeling the manure into the straw yard. The causeway court, in front of the byres, besides being convenient for carting in the turnips, affords space for the cows to move about in, or to stand in for a short time and, as the cattle always dung when they are driven out, by allowing them to remain for a few minutes in this passage or court, the manure, that might otherwise be wasted on the roads, is preserved, and thrown into the straw yard.

8254. The several drains leading from the byres, stables, and straw-yard, have such declivities as are sufficient to discharge the liquid manure into the tank, which is constructed on one side of the straw-yard in a central situation for the byres, stables, &c. It is thirty feet long, three feet broad, and seven feet deep; and, if the nature of the soil be porous, it should be plastered with Roman cement, to prevent the thin liquid manure from escaping. Being of this long and narrow figure, the tank can easily be covered with slates, which are much better than arched, and take up less space. The drains should have holes fitted with cast iron plugs, placed about fifteen feet apart; so that, if these openings a joined rod fifteen feet long could be put into the drain, with a hoe, or a piece of plate iron the shape of the drain, fixed to the one end of it. By these means the drains may be cleaned without breaking up any part of the causeway; but, if the drains are properly constructed, they will not require cleaning for many years. They should have a fall towards the tank, of at least four inches to the ten feet, and be nine inches wide, six inches deep at the sides, and nine inches in the centre. By having this kind of triangular bottom, the smallest quantity makes a current, and forces everything along with it. The drains through the straw-yard should have openings with grates (z z) over them, situated in the lowest part of the straw-yard, to draw off the surplus water after heavy falls of rain or snow. When these drains are not required, the grates may be easily covered over with dung; and if, at any time, the manure is found too dry, movable spouts may be attached to the pump which is placed in the tank, by which means the manure can be regularly spread over the whole straw-yard. A waste drain extends from the tank to an open ditch near the buildings: by which means, the liquid manure in the tank, if neglected, is carried off when it rises to that level, and is thus prevented from injuring the drains.

8255. The cattle sheds (p), from their situation, face the south, which is of great advantage to the cattle, though often overlooked in laying out farm buildings, and they are divided in the centre by a passage adjoining the turnip shed, and opposite the straw-house. This passage rises like an inclined plane four feet from A to B; the sides or paparets may be of wood, two inches thick (which forms the inclined turnip boxes), and be four feet in height, forming a space to both yards. All the manure from the feeding byre and stable is wheeled into the straw-yards by this passage; which, from its central situation, admits of the stable dung being equally distributed through both yards, and this by the rising passage can be done without opening a door, which prevents the one class of cattle from intermingling with the other, or getting out. Straw racks (h h h h) are placed in the sheds; but, by also having them in the centre
of the yard, and connected with this passage, they can be conveniently filled, and the cattle are induced to divide, which mixes the dung more generally through the yards.

825. The pigsties (e), from their situation, may be conveniently supplied from the kitchen or boiling-house, and are in both yards. Pigs are very beneficial to the manure, from their turning it over, and mixing it; they also eat up any particles of corn among the horses' dung that may not have been digested. One small enclosure is provided with a trough for feeding young pigs and the young spouts and grass growing on the cattle while eating; but they have no house or sty, that they may be induced to go out among the cattle, and to lie down among the stobs. By this arrangement, they have healthy exercise, and are enabled at the same time to eat and mix their food, and be beneficial to the manure in both yards. Another sty is provided for putting up a pair to feed.

825. The gates to the straw-yard may either be of the common form, or be hung, like sash windows, with stout ropes, pulleys, and weights. This last is perhaps the best plan as it secures them from the risk ofidge. As the dung is being carted out of the yard; and also enables them to be raised as the straw in the yard rises.

828. The cistern-house (a) is of such a height that pipes may be taken from it to the dwelling-house by means of a springer supplied from a small reservoir placed within the house; or a well may be dug, and a pump placed within the cistern-house. A water-trough is placed in the division wall between the straw-yards; and a ball-cock is fixed in the centre of the said trough, and shut in by boarding, overlapped by the upper part of the wall, which thus protects it from injury by the cattle at all times have the command of water, and none of it is wasted; if supplied from a spring, no attention is necessary, as the supply may be regulated by having a ball-cock in the cistern. Two troughs are placed on the outside, for the horses and the milch cows, and are also supplied with ball-cocks. The roof water, in the inside of the court, is carried round with spill-spouts, and with rainwater pipes at the south extremities, leading it into drains. It is a material object to carry off the roof-water, without allowing its admixture with the manure in the courts.

829. Estimate.—

The above estimate is made out upon the supposition that stone may be got for the working, at a distance not exceeding one mile from the building; and that the land carriage of the timber (which is all foreign) and of the lime should not exceed from five to ten miles, and that of the slates from ten to fifteen miles.

8290. Whin or furze fences strongly recommended as occupying less ground, and being ultimately cheaper than thorn fences. “Quick in growth, hardy, easy of culture in all dry, lightish soils, of unknown buty, and requiring under the knapsack, allowing an angle and a pleasing object to the eye, the best shelter for stock, adapted for food, and not suffering, but rather benefiting from being cropped.” Impressed with this conviction, W. Bell, Esq., of Huntthill, Roxburghshire, planted this fence extensively, and after a great number of years he is entirely satisfied with them.

(Trans. H. S., vol. xi. p. 471.)

8291. Wire and netting fences. An excellent substitute for hurdles or corn is manufactured every year at Whittington, Stoke Ferry, under the direction of Mr. Taylor, in the form of netting, and sold at very low prices. Messrs. Cottam and Hallen, of London, also manufacture a cheap netting for sheep folding from cotton waste. Mr. Taylor’s wire netting is particularly valuable for rendering garden and poultry-yard hedges impenetrable by rabbits, foxes, &c.

8292. Field gates. The most advantageous forms, and the lightest and cheapest materials, are pointed out by Mr. Buist, who recommends the thin, narrow, or pointed iron, or the stout, strong, or thickening wood.

He recommends wire gates of a very light construction, which cost from 10. 10. to 10. 16s. These are figured and described in the Gard. Mag. vol. for 1810, p. 193.; and in Trans. H. S., vol. xiv. p. 163.

8293-3104. A fall-down gate-stop (fig. 1174.) has lately been invented, which deserves adoption wherever double gates are fastened in the middle by a bolt attached to the lower bar, and entering a hole in a stone or other bedding except the road. This gate stopper is formed of cast iron, and is sunk in the ground with its upper surface level with the road, its lower end being placed on a stone to prevent its sinking too deep. The gate-stop has an angle which is raised up when the gate is shut, so as to form a stop, and a hole for the bolt; and it is put down (b) when the gate is open.

1174

To as not to present an obstruction to the feet of horses. Sold by Messrs. Cottam and Hallen.

BOOK V.

THE OPERATIONS OF AGRICULTURE. (p. 506.)

8294. The use of ploughing is for the purpose of loosening the texture of the soil so as to admit the free circulation of air and moisture, in order to promote the decomposition or disintegration of the stony parts of the soil, and facilitate the extension of the roots of plants in it. If you work the soil, you may drizzel it, you will never obtain the crops it is capable of yielding, unless you pulverise it; nay, so important did Jethro Tull think this, that he felt firmly persuaded that if you pulverised your soil well, you need not manure at all. Always bear in mind that the more valuable part of soil is that in which the active particles have not any direct influence upon vegetation; and you will then, at all times, be sufficiently impressed with the necessity of thorough plowing, harrowing, &c.; indeed, you may rest assured that, except upon some very light sands, you cannot pulverise the soil too much; economy alone must fix the limits of this useful operation.

Several chemical processes of considerable consequence as respects the fertility of soil, occur after it has been ploughed, which either take place very slowly, or not at all, while it lies unstrid; and, moreover, some of these take place to the greatest advantage during the winter. This is especially the ease with the disintegration of mineral masses, nothing tending so powerfully to reduce even the hardest stones to powder as sudden changes of temperature, combined with the presence of much moisture. During rain or thaw after snow all the clods of earth and the
pores of the more loosely aggregated stones become filled with water, which, of course, freezes, if the temperature is sufficiently reduced; and from its expansion during solidification, a peculiar property possessed in a marked degree by water, the particles of earth or stone, as the case may be, are pushed so far together, that when thaw returns, it crumbles into fragments, which are again and again acted on until reduced to the state of soil. This crumbling by frost is of the greatest importance in the case of stiff clays, for two reasons:—1st, because they are thus rendered much more easy to work; and 2d, which is of far greater consequence, they are enabled to give up their alkalies more readily to water; and clayey minerals are fortunately the quickest to disintegrate, or rather to decompose, by the action of the weather; and hence every means that facilitates that process is valuable, because, as we have already seen, those most valuable ingredients of soil, potas and soda, are of no use to plants, unless they are soluble in water, and they do not obtain this property until the mineral with which they have been associated becomes completely decomposed." (Dr. Madden in Stephen's Book of the Farm, vol. i. p. 461.)

PART III.

AGRICULTURE AS PRACTISED IN BRITAIN.

BOOK II.

GENERAL ARRANGEMENT OF LANDED ESTATES. (p. 558.)

8257. — 3759. Keeping parish roads in repair on the mile system. This system consists in putting "a certain portion or district of road under the sole care of one man, from which he is never removed so long as he conducts himself properly, and that the materials, instead of being carted and laid on the road, at the time of repairing, should be contracted for so as to be brought and laid on the sides of the road and trimmed up in one uniform way ready to be measured up some months before they are wanted for use." (Journ. A. E., vol. ii. p. 374.)

8259. — 3806. The perforator (fig. 1175.) is used as a substitute for the spade, in planting young tap-rooted trees in rough ground. It was invented by Mr. Munro, of the Bristol Nursery, and, in that

neighbourhood, in 1828, cost about eight shillings. In using it, one man employs the instrument, while another man, or boy, holds a bundle of plants. The man first inserts the instrument in the soil, holding it up for the reception of the plant; round which, when introduced, he inserts the iron three times, in order to loosen the soil about the roots; he then treads down the turf, and the plant becomes firmly set in the ground, which had been long planted. Two men may set from five hundred to six hundred plants in a day with this instrument. (Gard. Mag., vol. iii. p. 215.)

8274.—3971. Pruning forest trees. A digest of five essays on this subject, by Grigor, Gorrie, Cree, Fowle, and an anonymous author, is given in Trans. H. S., vol. xii. p. 141—175, which may be considered the most satisfactory article on the subject of pruning that has hitherto been published. All the writers agree in recommending a system corresponding with that of Mr. Cree's, but in some respects less definite.

8288.—4088. Increasing the durability of timber, by causing growing trees to absorb certain liquid solutions was tried by Dr. Boucher in France, and Mr. Hyett in England. (Trans. H. S., vol. xiv. p. 535.) The subject cannot be considered as yet settled: cresote and sulphate of copper appear to have been found most effectual preservative substances.

8272.—4092. Sawing machines for felling timber, of four different kinds, will be found described in the Highland Soc. Trans., vol. ix. p. 275. The most powerful of these appears to be a circular saw (fig. 1176) which, at the middle of the frame (a), in form of the common hand-saw, eight feet and a half in length by two feet and a half in width; on one side of which is erected a vertical frame (b b), of three feet and a half in height. The second compartment comprehends a traversing frame or carriage (c c) about five feet in length, and consequently the last to ripen; so that, if he waits till the whole crop appears ready for the sickle, all the early seeds will be too ripe, by the time that the late ones are sufficiently dry to cut; so that by this error in ploughing there is a direct loss, by the production of less flour from the early seeds, while the farmer is waiting for the late ones to ripen. (Trans. H. S., vol. xiv. p. 629.)
wheel (g) are in the proportion of one to five, so that, when the handle is turned with the ordinary velo-
city of forty revolutions a minute, the saw will make 200 revolutions in the same time. In order to keep

the edge of the saw in contact with the saw-draft, a vertical spindle (h), carrying the pulley (l), of one foot in
diameter, is placed at the outer edge of the carriage, or the carriage is thus made of the upper side of the
bar (g), slung over a smaller pulley on the winch axle. On the spindle (h) there is also fitted a small
drum (k), capable of being disengaged at pleasure from the motion of the spindle by means of a clutch.
The cord (l), which passes round the pulley (m), and, in the ground frame, has one end attached to a
spring that is pulled down by the winch, is carried, by means of a small pulley, to the other end of the
carriage, thereby carrying forward the saw with a slow and uniform motion. When the operation is completed,
the small drum is disengaged, and the cord is allowed to uncoil, while the carriage is moved backward to
prepare for the next cut. For the purpose of the simultaneous appearance of the cord to an acute angle
and guidance of the saw along the line, the carriage is fixed upon the lower part, which slides through eyes in
the ground frame; and the machine is kept steady while at work, by two iron dogs (grappling irons), the hooks of which are driven into the roots of the tree. The

certificates accompanying the model of this machine bear ample testimony of its success, and carried from tree to tree, by two men. The

machine being described is calculated for felling trees from eight to twelve inches in diameter. (Highland

Soc. Trans., vol. 18, p. 276.)

873. Species and varieties of the larch. That extensively cultivated by the Duke of Atholl is the

common white larch, \textit{Larix europaea Dec.}; but the following other species or varieties were tried:—

1. The Tyrol larch, with white flowers; those of the common variety being pink flowers. 2. The Tyrol

larch, with white flowers; the cones also remarkable for their whiteness, and for being erect, not

cerious. The shoots of the Tyrol larch are generally stronger than those of the common larch; but

the foliage of both kinds is similar. 3. The weeping Tyrolian larch, a variety of the common, with

pendulous branches; but distinct in botanical characters from the \textit{Larix pendula}, or black larch of North

America. 4. The red larch of North America, or \textit{Larix microcarpa}. This species is remarkable for the

great specific gravity of its wood, which is so ponderous that it will scarcely swim in water. Its cones

are shorter or smaller than those of the common larch, its branches weaker, and its leaves narrower.

5. The Russian larch, raised from seed procured by the Duke from Archangel, about the year 1686.

The bark is cinereous, not yellowish-brown; the leaves come out so early that they are liable to be

injured by spring frosts. The \textit{Larix pendula}, or black larch of North America, and \textit{Larix dahurica}

of Dr Fischer of Petersbourg, are distinct species, no examples of which exist at Dunkeld or Blair. (Hort.

Trans., vol. iv. p. 416.)

874. As an \textit{Appendix} to the chapter on Planting, we shall here give some account of the larch

plantation of Atholl and Dunkeld, from the \textit{Transactions of the Highland Society}, vol. vi. p. 165, to

p. 219. It appears that the Duke of Atholl planted 15,752 larches in 1814, and 37,531,600 plants.

Of these 8,604,942 plants were larch. All these were planted in the slant manner, as by far the best. It

is stated in that paper that the larch will supply timber fit for ship-building, at a great height above the

region of the oak; and that, while a seventy-four-gun ship would require the oak timber of seventy-five

acres, it would not require more than the ten timber of ten acres of larch; the trees in both cases being

sixty-eight years old. The larch in the neighbourhood of Dunkeld grows at the height of 1300 feet

above the level of the sea: the spruce pine at 720; and deciduous trees not higher

than 500. The larch, in comparison with the Scotch pine, is found to produce three and three quarter

times more timber, and that timber of seven times more value. The larch, also, being a deciduous tree,
instead of injuring the pasture under it, improves it. It is remarkable that the woody aphids, which

affected the larch plantations in most parts of Scotland for a number of years about the beginning of

the present century, never extended higher than about 600 feet above the level of the sea. The late Duke

John the Second planted, in the last years of his life, 65,000 Scotch acres of mountain ground solely with

the larch, which, in the course of seventy years from the time of planting, will put in rest of the

fit for the building of the largest class of ships in his Majesty's navy. It will have been thinned out

to about 400 trees per acre. Each tree will contain at least fifty cubic feet, or one load of timber,

which, at the low price of 1s. per cubic foot, only one half of its present value, will give accoun-

3,750 sterling. Besides this, there will have been a return of 27, per acre from

or, in all, a sum of 3,750 sterling. Besides this, there will have been a return of 27, per acre from

the thinnings, after deducting all expense of thinning, and the original outlay of planting. Further

still, the land on which the larch is planted is not worth above 6d. per acre. After the thinnings

of the first thirty years, the larch will make it worth at least six, the improvement of the

pasturage, upon which cattle can be kept summer and winter. (Highland Soc. Trans., vol. iii. p. 169.)

8275. Soil for the larch. It is an error to suppose that the larch will thrive in all soils and in all

situations. There are many kinds of soils in which it will not thrive, and ought not to be planted. It has

been found that in soils which have been turned up by the plough, and which have borne white crops,

the larch cankers. It cankers in wet situations also. In soils resting on a wet tilly subsoil, it decays at

the heart, after arriving at forty years of age. In situations where water stands for a length of time

above the roots, it becomes fogy, or covered with lichens. But in all rocky situations, and particularly

those which are composed of mica slate, containing crystal of garnets, among the fissures and fragments
of which they can push down their roots, larches thrive to adulation. The geognostic character of the soil is well suited to Blair isochor. At Blair isochor, clay slate; and the intermediate space is occupied by unca slate: they lie conformably to one another.

3276. Situation. The advantages resulting from planting mountain ground appear at first sight, in the greater number of trees that may be supported on the activity of a mountain than on a surface equal to it. The situation is exulted immediately on the soil in which they have been planted, and, as the superfluities of that soil must, of course, be greater on an activity than on the base, a greater number of trees will be there supported. Practically speaking, 100 trees, at six feet apart, can be planted on the hypothesis of a shameful ground: whereas the same amount planted in bluish, eight at the same distance. Another and a great advantage derived from planting mountain ground is, that, on an activity the trees expose a greater surface to the influence of the sun, and air, and rain, than they can do on a level surface. That trees derive much nourishment from the air, through the instrumentality of their leaves, there is no doubt. The experiment the better made, taking the lower fifty standing larches, in May, 1814, at Dunkeld, did not prevent their vegetation, and even forming wood for two years after. The outside trees in a forest are always the strongest. On an activity, they all possess the advantages of outside trees; and at the same time, most of the shelter enjoyed by those in the interior." (Highland Soc. Trans., vol. xi. p. 185.)

3277. Nurses were not used by the late Duke in his larch plantation. The gardener, in the Duke's abatement to his property, that Scotch pines are always best, and that by nurse trees, especially to the rate of Scotch pines, and that by nurse the larch the latter, that at the end of seventeen years they had not attained a height exceeding three feet; while the larches which they were intended to nurse were from fifteen to twenty feet high.

3278. The growth of the larch. Taking the average height of an average larch, of eight years from the seed, at eleven feet, it will be nearly accurate to allow sixteen inches as the annual growth, till the tree is fifty years old, and after that only ten inches per annum for twenty-two years longer; as the length of the tree leaves in growth as the bulk of the wood increases. These data give a larch tree of seventy-two years of age a height of ninety-three feet four inches; a fair average, agreeing with actual experiment. The shoots of larches beyond thirty-five years of age are heavier, though they are not so long as those of younger trees. The larch, like the oak, puts forth two shoots every year, the one in spring, in the other in autumn. The spring shoot has no lateral branches; the autumnal shoot pushes out like the one in spring; but, at the time this process is going on, the spring one is throwing out lateral branches which are firm and woody.

3279. In regard to the growth of the girth. A larch tree, on an average, will acquire an inch in girth per annum, in the first forty years from that time, and from that time, till it has acquired the venerable age of seventy-two years, it will grow one inch and a quarter in girth every year; thus:

In 24 years, it will be 2 feet in girth, at 1 inch per annum.
In 48 years more, 5 feet in girth, at 1 inch per annum.

In 72 years, it will be 7 feet.

3280. The larch begins to make wood at twenty-four years of age.
At 50 years old it will contain 26 cubic feet of wood.
69 14 ditto more.
72 — 20 ditto more.

In all, 60 ditto, or one load of 50 cubic feet, and 10 feet more.

3281. These results correspond exactly with the quantities which the Duke obtained at these respective ages. Larch appears to be on its greatest increase for timber from fifty-seven to seventy-two years old. A load of fifty cubic feet, or one load of timber, is quite fit for naval purposes. At half that size it is suitable for every country purpose.

3282. Thinning larch plantations. The great object of the Duke, in planting the larch, seems to have been to raise timber for naval purposes, and, finding that larches do not begin to grow at a size at twenty feet apart, he thinned accordingly. This distance gives 380 trees to the Scotch acre, or about one fifth of the 2000 originally planted. "The first thinning should consist of a light one of about one fifth of the whole, by removing only those trees that are of least value or worthless. After twenty-four years from the time of the first thinning, fall off the smaller branches, which are loose, and the first thinning is complete. From twenty to thirty years old, then, the thinning is carried on so extensively, as to remove two thirds of that which was left standing by the first thinning. In thinning, it is necessary to observe that all the stumps of the trees should be left if two or three feet, and if they are plainer than twelve feet. These small clumps happening to light on a favourable situation, they will thrive well, as of the air has access to each tree, around two thirds of its circumference. This thinning being delayed so long, the trees thinned out will be valuable for a variety of purposes. One of these purposes is the profitable use which may be made of the last thinning. The last thinning is made when the trees are from thirty to fifty years old, which will leave from 380 to 400 trees per acre." 

3283. Pruning the larch. Little or no pruning was used in the larch plantations at Dunkeld. The 380 trees left in the acre, it is observed, "require a little pruning and trimming of the lower branches, in order to give head room to the cattle, which are to browse on the grass below. The whole pruning and thinnings will cost about £1, and their produce will fetch about 12l., leaving a profit on them of about 7l. an acre." (Highland Soc. Trans., vol. xi. p. 190.)

3284. Thin planting the larch is recommended by the late Duke of Athol, because it allows the lower branches to extend to a greater size; and on these depend the thickness of the base of the trunk of the tree, and the strength of its roots. He therefore seldom planted more than 2000 plants per acre, more especially in the elevated and declivitous regions.

3285. The process of the thickening of the soil, and the improvement of the pasturage, by the larch, being very important in its results, it deserves to be particularly described. The lower and stronger branches with this root should be cut off, or so as to form a complete matting over the ground, which, together with the leaf mold, which lies throughout the annual deposit of leaves from them, by means of decomposition, forms, in the course of time, a soil of considerate depth. At the age of twenty-four, the larches lose the spines on the lower branches altogether, and that is the natural mark of their being ready to be removed by thinning, to a considerable extent. On the air being readmitted by the trees, the surface of the new-made soil, wherever it has been formed, even among the rocks, becomes immediately covered with natural grasses, of which the blue grass and ingle are Lady's bedstraw and H. lanatus, and H. lanatus, and H. lanatus, is put into the form of a narrow edge, with the help of haymaking. Then, which they receive from a continued deposition of leaves. The improvement of the natural surface of the ground for pasturage, by means of the larch, appears to be a proper peculiarity to this tree. This pasturage is quite capable of improving the condition of cattle, either in winter or summer.

3286. With regard to other trees effecting a change of the ground, the following are the results of many experiments made by the Duke on the subject. In oak copses, the value of the pasture is only 8s. or 6s. per acre, for oxen only, in every twenty-four years, 1 with the oak. In the Scotch fir plantation, the grass is not worth 6s. more per acre than it was before it was planted. Under beech and spruce it is worth less than it was before; but the spruce affords excellent shelter to cattle, either from the heat of summertime or the cold of winter. Under ash the value may be 2s. or 3s. per acre, but more than it was in its natural state. But under larch, where the ground was not worth 1s. per acre, the pasture is worth from 8s. to 10s. per acre, after the first thirty years, when all the thinnings have
SUPPLEMENT. AGRICULTURE AS PRACTISED IN BRITAIN. 1341

been computed, and the trees left for naval purposes, at the rate of about 400 to the acre, and twelve feet apart. Nay, so impressed was the Duke of the value of larch as an imposer of natural pasture, that he makes a statement to show that the pasture alone, independent of the ship-timber on it, would increase the value of the land, by increasing its annual rental, so that it itself would bear the whole outlay of planting and fencing, and planting, at five per cent. compound interest, thus:—

3600 acres of land in its natural state, not worth above 1s. per acre, at 25 years' purchase, £3,750 0 0.

Plants and planting, at 6s. per acre, 850 0 0.

2400 roods of fencing, at 5s. per acre, 600 0 0.

Sunday expenses, at 6d. per acre, 27 10 0.

£5,257 10 0

5872. 16s., at five per cent. compound interest, for twenty-nine years, the period at which the land is fit to be begun to be depastured, gives 21,594; but 3600 acres, at an improved rent only of 6s. per acre per annum, gives 19,090 4s. 8d. (Highgate, 1825, 113). 225.

5878. The value of larch wood, exclusive of the value of the pasture under it, may be estimated in this manner:—Suppose the plantations are thinned out by thirty years to what they are to stand for ship-timber. The 3600 acres are then cut down at the following respective ages: the value of the whole, per acre, at the different periods, would be as follows:

430 trees at 30 years old, at 2½ cubic feet each tree, = 1000 cubic feet, or 20 loads at 1s. 6d. per load, = 3600 0 0.

400 trees at 43½ years old, at 15 cubic feet each tree, = 6000 cubic feet, or 120 loads, at 1s. 6d. per load, = 450 0 0.

400 trees, at 50 years old, at 40 cubic feet each tree, = 16,000 cubic feet, or 320 loads, at 2s. 6d. per load, = 3600 0 0.

400 trees at 72 years old, at 60 cubic feet each tree, = 24,000 cubic feet, or 480 loads, at 2s. 6d. per load, = 4800 0 0.

The average of these prices would be £181 5s. per acre; so that 1000l. per acre is not too high a calculation of the value of the Duke's larch plantations.

5881. On felling large trees of larch, care must be taken to use plenty of rope, and to take advantage of the wind, whether in the wing: but on a day of heavy dew should be avoided. It was found, in digging the Scotch fir out by the roots from among the larch, that the ground was so much shaken that the roots of the larch, as to endanger their stability; ever after, the fir was cut over by the ground.

5882. Trees must be cut by strong trees, not by a fitter. In May, 1815, the Duke experimented on fifty trees of larch at Dunkeld, that were growing in a situation, among another wood, that was nearly inaccessible for want of a road or path to it. In 1846 they were cut down and used for several purposes, and they appeared to be completely seasoned. They contained twenty-five fire cubic feet of wood each. Larch trees that had been only ten months cut down were built into a steam-boat in the river Thames, but they had not been seasoned enough, as the planks above water, near the deck, shrunk a little. In this case, however, the scuttles were made the same as of oak, with the same diameter, and no slight dimensions of the timber.

5882. Uses of the larch. These are various. Larches have been grown by the Duke as nurses to spruce firs. The thinnings of larch plantations, "which take place from twenty to thirty years of the age for ship-timber" were found useful for fencing purposes, and for building out of the tops or the trunks of young trees. White fir-posts and rails last about only five years, and are worn- eaten after that period, the larch- posts stand for twenty years, and never get worm-eaten. But the trunks of young trees are preferable for this purpose to the tops, as they have less sap-wood. In 1867 the Duke fenced a nursery-ground with young larch trees cut up the middle, made into a railing seven feet high. In three years after, the sawn side assumed a brown grey colour, and in 1871 the whole railing was quite sound. Larch tops which had lain cut for four years, and were, of course, well worn, were found useful in filling drains where stones were at a distance, and they continued in use for many years. The larch was used for axles to different kinds of mills from 1793 to 1862, and up to 1817 continued quite sound, though constantly in water.

5883. For buildings, too, the larch is found equally desirable. In 1779, the Duke built the shooting-box in Glenflett and Forest Lodge, the parts of which were made of larch. The wood was under forty years old, and, as an experiment, some of the deals were cut up narrow, and others as broad as they could be wrought. In 1847 the narrow boards continued quite close together. After the bridge was thrown over Dunkeld and the course of the great northern road was improved, a girder was made, which caused him to build a new porter's lodge, stables, and offices to Dunkeld House, near the new line of road. The whole wood-work of these buildings was executed with larch. They were finished in 1812. In 1815, part of Athol House was built down, and it answer for that purpose. It was the Duke's practice to plant spruce in all the wet parts of the ground, which he planted to the amount of about one tenth, expressly for the purpose of raising mats and spars, for which he conceived the spruce peculiarly well adapted.

5892. The larch has been tried for masts; but, the vessels which were fitted up with them having left the Tay, it is uncertain how far larch timber will answer for that purpose. It was the Duke's practice to plant spruce in all the wet parts of the ground, which he planted to the amount of about one tenth, expressly for the purpose of raising mats and spars, for which he conceived the spruce peculiarly well adapted.
The larch as plices. Two hundred and twenty-three trees, forty-two years old, were converted into piles, and driven into the river Thames in the front of the works of the Woolwich dockyard in the year 1810. A report on their state was made in 1817, when they were found to be as fresh as if they were newly cut. It is impossible to produce this paper without being strongly impressed with the patriotic views entertained by John, the second Duke of Atholl. Living in a period when the country was involved in a war with almost all other countries, he dreaded, in common with other patriots and statesmen, a scarcity of timber fit for naval purposes, and he contemplated the idea of planting so extensively as to provide against this scarcity for centuries to come. In all his plans and operations we see little or nothing of the merely selfish principle at work; his great object was to provide a regular yearly supply of ship timber, the commencement of which supply could not take place till many years after he was dead.

The following table shows the Duke’s own calculation of the supply which would be afforded by the woods of Atholl, from 1832 to 1964.

289. The relative duration of timber has been thus determined by M. Hartig, an eminent German professor of forestry. Small plots of lime tree, black American birch, alder, and trembling poplar, intersected in the soil, decayed in three years; the common willow, horse-chestnut, and the platams, in four years; the purple beech, and the common birch in five years; the elm, the hornbeam, the ash, and the Lombardy poplar, in seven years; the acacia, the oak, the Scotch pine, the Weymouth pine, and the spruce fir, at the end of seven years were only depredated a little by the roots of a fur-tree; and the larch, the common juniper, the Virginian juniper, and the arbor vitae, were, at the end of the same period, untouched by decay. Thin boards of the same woods decayed in the following order: platams, horn-beam, elm, birch, larch, horse-chestnut, common birch, Spruce, the elm, the Weymouth pine, the acacia, and the larch. (L’Agronomie, tom. i. p. 315.) It thus appears that the larch, whether as posts with the bark on, or sawn up into boards, is by far the most durable of our timber trees.

BOOK III.

IMPROVING THE CULTURABLE LANDS OF AN ESTATE. (p. 690.)

2898—4213. Draughting by steam power. The application of steam power to the draughting of land which the ordinary means of draughting are insufficient to accomplish, is among the most important improvements of the time. Land which, otherwise, either could not be cultivated, or with the uncertainty of reaping what was sown, is now cultivated with profit and certainty by the locality of which steam power is applied. In the British Farmer’s Magazine for 1839, and also in the Transactions of the Society of Arts of that year, will be found a detailed account of the steam power draining which has lately been effected in Cambridgeshire and Lincolnshire. It will be found of the greatest interest to those possessing similar tracts of land. The water is lifted with wheels and raised about 35 feet higher than the surface, at which height it flows off to the rivers or main drains.

2899—4267. The frequent drain system. The great importance of thorough draughting, and deep ploughing, has lately been placed in a striking light of view by Mr. Smith, Esq., platinographer of the Exhibition of Agricultural Productions, &c., published in 1832, by Messrs. Drummond, seedsmen, of Stirling. Mr. Smith observes, “that the practical drainers of the old school cannot see how a field should be drained, unless by deep cross drains, to cut off the springs. The result, however, of the great water springing at the surface to that which is in a wet state from the retention of the water which falls upon the surface in the state of rain, and a vast extent of the arable land of Scotland and England, generally esteemed dry, is yet so far injured by the tardy and imperfect escape of the water, especially in winter, and during long periods of wet weather in summer, that the working of it is often difficult and precarious; and its fertility is much below what would uniformly exist under a state of thorough dryness. A system of draughting, therefore, generally applicable, and effecting complete and uniform dryness, is of the utmost importance to the agricultural interests, and, through them, to all the other interests of the country. By the system here recommended, this is attained, whilst the expense is moderate, and the permanency greater than on any other system yet known. The drains, as applied in the case, have been named wedge drains, from their form, and being filled with wedges or keys to preserve the opening in their bottoms. They are sometimes called sawdred drains, from their being placed under the water furrows of the ridges; but these terms give no exposition of the principle upon which the effect of this mode of draining depends. The principle of the system is, the provision of frequent opportunities for the water rising from below, or falling on the surface, to pass freely under, or completely off; and, therefore, the most appropriate application for it is the frequent-drain system.”

3000. Main drains. In proceeding to apply this system of drainage to land, the first object is to obtain a position for the main drain, as it is properly termed, for a number of separate systems, from various smaller or ordinary drains. This drain should be directed along the bottom of the chief hollow or valley of the grounds, where the whole or greater portion of the drains can be led into it. If any lesser branches of surface water must also have their drainages into the bottom of the main should be at least three feet; and, if possible, three feet and a half or four feet under the surface where it passes along; and it should have throughout as uniform a fall as the nature of the ground will admit. It should be flagged at the bottom; or, where flagstones are expensive, built as an inverted arch, cordon over the slope of the bottom, &c. with the long sides near the head, and the short sides near the tail. Dimensions necessary will depend on the fall or declivity, and the area of land from which the drain has to receive water. With a fall in no place less than 100 yards, a drain ten inches wide, and eighteen inches deep, will effect the rain water flowing at the rate of 100 acres. It is of great importance to make the openings of such drains narrow and high; as they will thus require smaller bottoms and covers, and be less liable to give way; the current of water being also more confined, mud, and sand will be less apt to settle in the bottom. Let the sides be smoothly and securely built with flat stones, either with or without mortar; and let strong flat covers be placed over the drain; or, where such are not to be found, a rough plastering, with thin stones and mortar, may be built, packing the joints of the arch well up to the sides of the cuts with earth beaten in firmly. Where lesser hollows occur, crossing the fields, it is necessary to cut sub-drains along their bottoms, about three feet or three and a half feet deep, and having openings of suitable dimensions, either formed by stone couples (two flat stones placed together at the top and apart at the bottom, like the two sides of a triangle), or with drain tiles; or, where a very large flow of water has to be provided for, with inverted tiles, and covering tiles placed above the bottom one, or with larger tiles made on purpose.
(331. Submain drains. There should be a cross submain at the bottom of every field or stretch of drains, deep enough to drain the field, and such submain drain should always be six inches wide. These drains can be executed at any season when the weather will permit; but spring and summer are more suitable for the work. It is best to execute the drains when the field is in grass, as they can then be cut in all kinds of weather, and in a more cleanly manner.

(380. In setting out the drains, the first object for consideration is, the nature of the subsoil: if it consists of a stiff strong clay, or a dead sandy clay, then the distance from drain to drain should not exceed twenty-four feet, but if it is a lighter and more porous subsoil, a distance of from eighteen to twenty-four feet will be close enough. When the ridges of the field have been formerly much raised, it suits very well to run a drain up every furrow, which saves some depth of cutting. At whatever distances the drains are placed, they should be parallel to the ridges. In the deepest depressions they could always be run quite parallel to each other, and at regular distances, and should be carried throughout the whole field without reference to the wet or dry appearance of portions of the field; as uniform and complete dryness is the object, and land, which may be considered dry in its natural state, is apt to be in all kinds of weather, and in a more cleanly manner.

(381. Excavation. The line of the primary drain can be marked by cutting a trench a little more than the depth of the drain, the drainer begins by cutting a trench with a spade on a line; then removing the first layer to the depth of a spitful of about thirteen or fourteen inches wide all along, another follows with a narrower and tapering spade, made for the purpose, taking out another layer; and, when picking becomes necessary, a third man follows with the earth, and a small or scoop shovel is used to clean out the foot of the drainer, and a small or scoop shovel is used to clean out the bottom, which should be cut as narrow as will allow the last drainer a footing, generally about three or four inches. From two to two feet and a half from the surface are the best depths for such drains; the latter always to be preferred. The drains should be cut as straight and uniform as possible, so that the water may flow freely along all at places, and it is better to cut a little deeper when there is any sudden rise of the surface than to follow it; and where sudden hollows occur, the cutting may, on the same principle, be less deep: attention to this also admits of saving straying or levelling of the surface, which is necessary to the economy of the work. The worksman may also throw the earth to the right and left from each alternate drain, as that allows the plough to go regularly and fully occupied bountings (a Scotch term for a rotation or traverse of the plough) in filling the earth, while each alternate ridge or space is left for gathering the free from the ground out.

(895. Filling. The stones may either be laid down at intervals, by the sides of the drains, to be there broken; or, being broken in masses at some convenient spot, can be brought by the carts, ready filled, to be placed in the cutting. No part of any drain should be allowed to be covered until the whole is laid. After being laid, the drains are filled, after having been cut, the better. Sometimes, when there is much tendency of the sides to fall in, it becomes necessary to fill in going along. Cutting at the end of summer, when there is little water in the soil, or in a dry season, saves much of trouble. In soil or sandy in its mass, by cutting the drains to half the depth in the first instance drained land, it is apt to be in all kinds of weather, and in a more cleanly manner.

(387. The cost of executing such drains varies, of course, according to circumstances: the cutting cost (in 1829) from 1s. 6d. to 2s. 6d. per rood of a distance of thirty-six yards. According to the hardness of the subsoil; the stones, if collected on the adjoining fields, will cost from 1s. 6d. to 2s. 6d. per rood, and from 1s. 6d. to 2s. 6d. per rood; but one and a half cubic yards of broken stones will fill a rood of a well drained; the putting in of the stones must be calculated at about 3¼s. per rood, and the turfing about 6d. per rood. The whole cost, per rood of a distance of thirty-six yards, will be about 13s. 6d. per rood. The putting in of the turf, and the covering over the stones with the plough will cost about 6d. per rood. The whole cost, per rood, of a distance of thirty-six yards, will be about 13s. 6d. per rood.

The following table exhibits the cost of a Scotch acre of a field, 26 chains by 8 chains, at various depths, and under various circumstances of drainage, and is calculated from the ploughing and levelling necessary to form the level, and getting in the horses and cattle, &c., which can be performed by the tenant, will cost, charged at the ordinary rates:-

- | Subsoil to which the Distances are applicable. | Distance between the Drains in Feet. | Roods per Acre. | Cost per Acre to Landlord. | Cost per Acre to Farmer. | Total Cost per Acre. |
---|---|---|---|---|---|
| For stiff clay subsoil | 4 | 4 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 4 | 4 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 6 | 6 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 8 | 8 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 10 | 10 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 12 | 12 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 14 | 14 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 16 | 16 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 18 | 18 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 20 | 20 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 22 | 22 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| | 24 | 24 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |

For sandy clay | 15 | 15 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| 16 | 16 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
| 17 | 17 | £2 6s. 6d. | £2 6s. 6d. | £5 3s. 6d. |
Free strong bottom

More open bottom

Irregular beds of gravel or sand, and irregularly open rocky stratifications

Remarks. In cases where time or capital are wanting to complete the draining, each alternate drain may be executed in the first instance; and the remainder can be done the next time the field is to be worked, so that the drainage field has been completed, after which it may be needed immediately after that crop is off the ground, the field should be thoroughly over with the subsoil plough, crossing the line of drains at right angles.

The subsoil plough has been constructed on principles appearing the best fitted to break up the subsoil completely to a depth sufficient for most thorough cultivation, say fourteen to sixteen inches, allowing the active soil still to remain on the surface; too of the easiest possible draught, in reference to the depth of furrow and firmness of the soil, and to the strength and effective weight sufficient to penetrate and resist the shocks from fast stones and to throw out in the direction of the wind, under 200 lbs. in weight. All this has been accomplished, and practically proved, over an extent of at least 200 acres of various soils. This plough requires four good horses, a strong ploughman, and a lad to drive the horses and manure hopper. In the turnings, when the six horses, yoked three and three abreast, may be necessary in some very stiff or stony soils. A common plough drawn by a pair, goes before the subsoil plough, throwing out a large open furrow of the active soil. The subsoil plough following, stirs up thoroughly and breaks the bottom, when the next furrow of the active soil is thrown over it; the next furrow is drawn over the top of the preceding furrow, and breaks the surface by the subsoil plough being thrown aside, on the ploughed part of the land, by a boy or lad; and so on, till the whole field is gone over. The boy should carry a bag of wooden pins, that he may mark the site of the large fast stones which the plough cannot throw out, and which must afterwards be dug out with pick and shovel, blasted. This large plough is a sort of horse-pick, breaking up without raising to the surface the subsoil. Channels are thus regularly formed for the water to flow from all parts towards the drains. The atmospheric air being also by this means freely admitted to the subsoil, the most sterile and obdurate clay becomes gradually aerated, and the common plough may ever after be brought to a depth of from fourteen to sixteen inches without obstruction; and with the power of three horses yoked abreast, and managed with ease by the ploughman, without any person to drive. By being thus taken together, and near the point of resistance, the horses have great power; and, the furrow turned over being broad in proportion, nearly as much grave as nine to twelve of barley; the head and part following being also very fine. When fields have been thus dried and worked, it is recommended to plough them at all times without ridges, or water furrows, preserving uniform sheet of soil over the whole field.

The effect of this mode of draining and deep working on close-bottomed land is quite wonderful. After one turn of green cropping, with the usual application of time and dung, the formerly scanty sterile surface soil becomes a deep rich loam, carrying, without fall, crops of wheat and barley, producing from nine to twelve of barley, and even from eighteen to twenty of barley land; the residue of the roots being being also very fine. When fields have been thus dried and worked, it is recommended to plough them at all times without ridges, or water furrows, preserving uniform sheet of soil over the whole field.

The effect of this mode of draining and deep working on close-bottomed land is quite wonderful. After one turn of green cropping, with the usual application of time and dung, the formerly scanty sterile surface soil becomes a deep rich loam, carrying, without fall, crops of wheat and barley, producing from nine to twelve of barley, and even from eighteen to twenty of barley land; the residue of the roots being being also very fine. When fields have been thus dried and worked, it is recommended to plough them at all times without ridges, or water furrows, preserving uniform sheet of soil over the whole field.

water, will best attain their object when made straight up and down the slope. The reason is thus given by Mr. Smith of Deansdon: "Drains drawn across a steep, cut the strata or layers of soil transversely, and as the stratification generally lies in sheets at an angle to the surface, the water passing in or between the strata, immediately below the bottom of one drain, nearly comes to the surface before reaching the next lower drain. But as water seeks the lowest level in all directions, if the strata are generally directed normally by a drain directed down the steeps, the bottom of which cuts each stratum to the same distance from the surface, the water will flow into the drain at the intersecting point of each sheet or layer, on a level with the bottom of the drain, leaving one uniform depth of dry soil." (Remarks on Thorough Deansdon, p. 9.)

8314. *Tide draining* has the great advantage of sifting every soil, from the poorest to the richest, and of being used at any depth, and where stones cannot be applied, as in morasses or flour-moss. It is less expensive than stone draining, and equally, if not more, durable; for a tile should give way if it can easily be replaced, or a whole drain re-opened and renewed at pleasure; which is impracticable with stones. Besides, being more portable, tiles can always be had of any size, shape, or strength desired, in those clayey districts where stones are wanting. Thence, therefore, are tiles substituted for stones in ordinary draining. Shut up from the influence of the weather, and secured from every injury, it is impossible to limit their duration, or conceive anything better calculated for the purpose of draining. In consequence, almost the whole of the drain has very little slope, below the decided preference to be had, and ought, therefore, to be used in such situations, even though they prove more expensive than stones. (Trans. H. S., vol. xii. p. 81.)

8315. *Concave drain tiles*, have been made by Lord James Hay, and the mode of operation is most distinctly described and illustrated in the *Transactions*, vol. xiii. p. 138. It might therefore be attempted with any prospect of success where there is strong quick setting lime and sharp sand. Perhaps peat may be advantageously compressed into draining tiles.

8317. *The substitution of larch-wood tubes for drain tiles* has been adopted by W. Scott, Esq., Craigmoy, Kirkcudbright. The tubes are 4 inches square externally, with a clear water way of 2 inches. They are put together with wooden pins or nails, as may be found most economical. (Trans. H. S., vol. xiv. p. 164.)

8318.—4330. *A tide sluice*, invented by the Rev. George Cruden, is represented in figs. 1177 and 1178.

[Diagram 1177]

The float is then raised by its buoyancy in the tidal water, and so closes the passage through the spout a, preventing either the entrance of the tidal water or the escape of the water of the pond, and admit it at pleasure, with as much accuracy and ease as a brass cock does the contents of a beer barrel.

8319.—4066. *Sluices, trunks, and values for embankments* are now made of cast iron, on an improved principle; and, when properly fixed in by a mass of masonry and cement, they are found to retain the water of a pond, and admit it at pleasure, with as much accuracy and ease as a brass cock does the contents of a beer barrel.

8320.—4455. *Artesian wells*, or those produced by boring, are so named from their having been first used in the neighbourhood of Artes in France. Upon a review of the apparatus employed in them, it will be evident that they must always succeed where an inclined stratum of a fissured or porous limestone, or other porous stone, is included between two waterproof beds of clay; one of which sets a limit to the sinking of the water downwards, and the other prevents it from rising sideways into the fresh water collected in the reservoir, until the flood-tide has risen so high as to envelope the float in its water. The float, not being stopped by the buoyancy of the tidal water, will thus pass through the spout a, as if it were not there, and the water will distill through the stratum of clay or soil between the float and the bed of water, by which advanced a new stratum of water is washed up through the spout, and will be collected in the reservoir, as if it were the surface of the water, which is raised to a level immediately above the spout. Thus, the rise of the tide is in the same manner as if there were a perfect connection between the ground water and the surface; and it is evident that the underground strata will be agitated, or that there is a communication between the surface and the subsurface water. This mode of operating the apparatus is as follows: A waterproof stratum of clay must always be left in front of the float, before reaching the springing water; and it may easily be conceived that the undermost layer is never wanting. Although, for the most part, some thinner strata of limestone supply its place, yet the strata which conduct the water always contain it in cavities, which are always open through the surface than in the centre of the beds. Thus, there is a demonstration, as in a boring work at Blengel, that, even in the limestone itself, beds of clay occur. From these circumstances it is easily explained how we can never hope to sink Artesian wells in granite, granitic porphyry, serpentine, &c.; and, even in schistose mountains, it would be quite impracticable to sink these wells, because, if water were found there, it would be very easily impregnated with sulphured hydrogen, from the abundance of pyrites occurring in these strata, and thus be unfit for many uses. Limestone, on the contrary, is fitted by the very nature of the cases, as we have just seen, to be so employed, and to effectually yield us a fresh water. These observations especially relate to the Pas de Calais.

8321. *Other districts*, where water has been bored for, show a similar geognostic constitution to the Pas de Calais. M. Garnier, in the *Memoire sur la Fontaine-soudiere de Paris*, notes this, the Boston in the Fontaine-soudiere of Paris, is known to be situated in a district whose ground water have, for a long time, been principally supplied with water from Artesian wells) lies in the middle of a basin-shaped hollow, the fundamental rock of which is a limestome, and to which it is connected by the clay, which is covered with clay, though at times not immediately. The wells, which are sunk to this London clay, give abundance of clear, but mostly very hard, water; while those which penetrate through the London clay, into the subjacent strata, are of a decided character and consist of clay and boulders, yielding a water of soft and pure water, which, on piercing this clay, often ascends with such violence that the workmen have scarcely time to escape. Here the plastic clay seems to be either the conducting medium, or the reservoir of the water yielded by the chalk; for Paris is known to be situated in a district whose ground water is mostly impregnated with sulphured hydrogen, so that there, as well as in many other parts of the north and east of France, Artesian wells may everywhere be sunk; nor can we doubt of the extension of this very useful discovery. (Janoucet's Phil. Trans. for July, 1830.)

8322. *We must not, however, expect to be able to sink Artesian wells in every description of country*, as has been thoughtlessly asserted. On the one hand, the nature of the ground sometimes absolutely prevents it, as in granite districts; and on the other hand, it is possible that a perforation, if made too near...
a bored well affording water, may not yield any; should the latter, for example, be fed by a subterranean current, in place of being supplied by a sheet of water; or should the perforation be made on the extremity of a basin with inclined strata, resting upon a formation of a very different nature. M. Girard's 'Manuel du Fontainier-sommaire' contains all that can be desired on the subject of boring these wells. (Ibid.)

532. General observations on Artesian wells. Great subterranean sheets of water exist at various depths in the earth. - It is frequently met with in the position of strata of different consistencies. They, however, frequently occur at various heights in the great masses of earth, as those of clay, chalk, and even marl or limestone containing chertina, when these masses are entire and of great thickness. According to the slope, the inclinations, or the declivities which are presented by the plan of the country in which the artesian deposits intervene, it is probable that these great sheets of water are met with at all depths; but it is impossible to lay down any constant rule with respect to them. (Ibid.)

In order that these waters may be capable of ascending, it is necessary that the formations among which they occur be entire, in the state in which they were originally deposited; and that they be not intersected by valleys, or deep ravines, through which the waters would find a free and easy exit.

535. It would be in vain to search for springs in deposits which, at no great distance from the place of boring, are intersected by deep valleys, or where the formations are internally crossed, filled with tortuous separations, and greatly disturbed, whether by the contraction attending the desiccation of the mass, or by internal shocks, swellings, or earthquakes; or, lastly, when these Neptunian formations, such as plastic clay, chalk, oolite, and shell-limestone, are raised up, and present precipices at the surface. In such localities, we need not expect success in boring for springs, unless by penetrating deeply into the mass of the chalk, in search of the sheets of water in its lower part; or even by traversing it entirely, in order to come upon those in the clays, oolites, and shell-limestones, which are raised in the latter, when they happen to be raised to the surface, and to present cliffs, or are intersected by valleys of greater or less depth.

536. In a country comprised of elevated plains, if, in place of boring to the necessary depths for reaching the different water-sheets which are commonly the most abundant, and, at the same time, those which rise highest, the boring is stopped at higher levels, less distant from the surface, it is more than probable that boring at the orifice will stop more on the ground, according to the depth of the borings. When this occurs, we ought to be far from considering the operation of boring as having failed; because in this case the water does not rise above the surface, and in most instances, according to the localities and the nature of the ground, steps may be taken to remedy the deficiency. For example, when the water of a borewell is not sufficient for the supply of the surface, but in sufficient quantity, it might be conducted from the point to which it reaches, by a small gallery, into some neighbouring well, or into one dug on purpose; and there might thus be produced a hydraulic fall, which might be employed, as a ground, and even beyond it, by employing for this purpose either the hydraulic ram (bölier hydraulique), which would always give a third of the volume of water, or a wheel, which might be placed at the point of the fall, and which, working a pump suitably placed, might raise the third, or perhaps even the half, of the quantity of water thus hydraulically raised; or, in the case of the other, it might be practicable only in so far as the wells into which the waters should be precipitated might not allow them to run off into strata of permeable deposits.

537. In such circumstances it is necessary to examine and appreciate before resolving upon boring a well. It is necessary to examine the physical constitution or the nature of the ground, and the disposition of the surface of the country, with reference to the mountains which overlie it, the valleys by which it is intersected, and the springs which rise in those valleys. The latter it is particularly necessary to examine, before making a well, on the ground of it being a well, as it is necessary to select a fit person for boring; the art not being merely mechanical, and such as can be practised by any borer. Besides attending to these circumstances, it is necessary to be possessed of perseverance and courage, which will lead us to disregard the delays and difficulties often unavoidably connected with the operations of boring. (Héricart de Thury, as quoted in Jameson's Journal for July, 1830.)

539. Boring for water in deep sand. Mr. David Greenley, of London, has been lately (August, 1834) successful in obtaining "a distant supply of water" at a depth of upwards of 600 feet below the surface. A well had been previously sunk in the same place; but, in consequence of an immense quantity of sand rising whenever the pump was worked, it was almost useless. (See Arch. Mag., vol. i. p. 210.)

540. The improvement of waste lands, whether moss, bog, or wet clay is exemplified in seventeen different cases reported on in the Highland Society's Transactions, vol. x. p. 281. The article embodies an amount of valuable practical information on the subject.

541. Drilling rocks or soft sand. A newly invented instrument has been brought into notice by Mr. D. Millar, road contractor and builder in Edinburgh. The apparatus appears to be a more efficient boring instrument than any hitherto in use. It is calculated to bore or tap to the depth of 100 feet or upwards, and may be put in operation either by manual labour or steam. (Scotsman, Feb. 22, 1834.) An instrument for the same purpose was invented by Mr. Mallet of Dublin in 1832. Mr. Mallet's object was to split all rocks which could be separated into laminae, by the application of the male and female screws; instead of blasting, as heretofore practised, with gunpowder. The process is as follows:—1. Jumper holes are formed in the direction of the proposed fracture, as at present; but, instead of filling these with gunpowder, a split female screw is inserted in each hole, and the fracture is effected by the insertion of a conical or male screw. (Arch. Mag., vol. i. p. 93.)

543. Draining and boring into cultivation moss-lands or peat-bogs. The Liverpool Agricultural Society having awarded its premium to Mr. Redd, late of Chat Moss, but now a professional drainer, we give the following as the essence of his paper. We may premise that we had the pleasure of inspecting Mr. Redd's farm at Chat Moss, near Liverpool, in August, 1831, and were much gratified and interested, when there, to see the new and old drains, and the moss still growing on the paper. (Ibid.)

544. Draining. The water, to a considerable depth from the surface, being held in a great degree by capillary attraction, drains should be frequent, and more or less distant according to their depth. Open drains, or drains at a distance from each other, should be placed at any depth below the surface of 100 yards. The covered drains should run at right angles to the divisional drains. Sixty-six yards, or three chains, Mr. Reed has found the best width between the open drains; and, consequently, as the covered drains are at right angles to these, the length will be sixty-six yards. The open drains may be four feet wide at the top, from one inch to one foot six inches wide at one foot four inches deep. The depth of both should not be more than five or six yards apart, and three feet deep. No material is wanted to cover them but the moss itself. "The form should combine the principle both of the shoulder and the wedge drain, which is somewhat square ced, which is first taken out, when dried to a certain extent by the weather, becomes the cover." (Ibid.)

533. Preparing the soil. "Moss, or peat bog, is not a soil, but an accumulation of dead, dying, and decaying plant matter, growing in water; and is to be destroyed, to a certain degree, by the depth, the original structure of the moss, both for the purpose of destroying vegetation, and facilitating the passage of the water to the covered drains. Digging is perhaps the best mode of destroying the structure of the moss, and afterwards, a cutting machine formed by fixing circular knives on the cylinder of a common roller, may be applied. In due time, the surface may be harrowed, and afterwards manured,
and sown with a crop. Any description of harvest is useful, as tending to consolidate the moss, and to facilitate its decomposition: but, to obtain a good crop the first year, putrescent manure in a considerable quantity is absolutely necessary.

3831. *After cultivation.*—"Manure of some sort being applied, almost any description of crops may be had; but potatoes are perhaps the best article to begin with; 2d, wheat; 3d, clover, without grass seeds; 4th, oats, and with a little winter wheat, include almost every article of produce."

3835. *The preparation of coke or charcoal from peat or moss has been effected in different parts of Scotland, and in Ireland, and the charcoal thus produced has been found superior to many kinds of coal for certain purposes.* This arises from the high proportion of the total elements, of charcoal matter in the peat, which renders it almost equal to the charcoal of wood, to which it is well known the Swedish iron owes its principal excellence. The charring of peat for use in smelting iron has been strongly recommended as a means of giving employment to the labouring population. (See Brit. Farm. Mag., vol. v. p. 996.)

3836.—*4992. Ripening corn.* It is important, Dr. Madden observes, that the process of ripening after the seed has filled, should be as rapid as possible. "When the ear first fills it appears composed almost entirely of water; and about a fortnight after this, if we again examine it, we shall find the seed much more solid, the milky juice having hardened and consolidated, and the straw beginning to wither, which it always does from the ground to the ear. At this period the straw will be entirely yellow; and another fortnight from this will be perfectly ripe, that is to say, the straw will be uniformly yellow up to the ear, and the chaff will be sufficiently loose to admit of the grain being rubbed out by the hands. On examining the ear, the most perceptible difference which has taken place since the last period is, that the skin has become much thicker and harder, while the grain may be seen distinctly through the enveloping skin, and the seed is an increase of bran, and a relative diminution of flour, which change increases materially, according to the length of time that elapses between the ripening and the harvesting of the crop." (Trans. Inst. 1838. p. 129.)

3837. — *4991. Diseases of Corn.* Professor Henslow delivered a learned lecture on this subject, the essence of which will be found in the Gard. Chron. 1841, p. 5.

3838. *The smut fungus (Uredo cæris Dec.)* is called also smutballs and pepperbrand, may be described as a pestiferous and destructive insect, attacking the only corn it attacks. The effects which it produces are as follows:—The alkali of a number of substances, such as potash, lime, &c., produce in destroying the smut, when seed or corn is dressed with these substances, is supposed to owe to their forming a soapy compound with the oil of the fungus, which is then more easily detached from the surface of the corn, to which its natural greasiness makes it adhere.

3839. *The smut or dust-brand (Uredo ségetum Dec.)* is a fungus which differs from the last in its habit of growing in different sides of the infected grain in the form of a whitish powder. It rarely attacks wheat, but is a common enemy of oats and barley. The usual palliative of this evil is steeping, as in the case of the burn.

3840. *Rust (Uredo ruminó Dec.) is a fungus resembling an orange powder, exuding from the inner chaffs, and forming flat blotsch or brown spots on various parts of corn plants; but it is a pest of comparatively small importance; but Professor Henslow has made the very curious discovery that it is the young of the mildew, the Puccinia graminum of botanists, which is so destructive when it attacks wheat, and the black spot of apples, and is found at the base of the leaf and the base of the Uredo or rust; but by degrees the spheres lengthen, acquire a stalk, contract in the middle, and so form the head of the Puccinia; so that two supposed distinct species, Uredo and Puccinia, are undoubtedly in different stages of development."

3841. *Ergot* was regarded as a monstrous state of the grain of rye, produced by the external action of a minute fungus, which causes the grain to lengthen into a horn something like a cockspur. It is so exceedingly oily that it will burn like an almond in the flame of a candle. The action of ergotised corn has been described by both man and animals; the latter, indeed, preferred starvation to feeding upon it, even when mixed with good flour. A duck which had been fed with ergot mixed with flour, in the proportion (say) of 1 in 17, died in ten days, after having had the end of its tongue burnt off, and died of its poisoning from its nostrils. A pig was poisoned by eating fifteen pounds of ergot mixed with flour in twenty-three days; the ears and the flesh of the tail having rotted away, and the legs having mortified. Fortunately we know little of this pest in England; for it is equally fatal in its horrible effects upon man, as has been amply proved in France. Draining is considered as the only known preventive of ergot.

3842. *Ear cockles are produced by an animalcule called the *Vibratio tritici,* which may be compared to the *rats* in paste on a small scale. They form a cottony mass in the interior of the grain, which, when the corn is first broached, passes out, but is retained in the back of the ear by the weight of the head. The creature is microscopically small when young, but it grows at its full growth, becoming a quarter of an inch long. Nevertheless, Mr. Bauer has calculated that 50,000 of the young might be contained in one grain of wheat. The pest at which corn crops appears to be produced by these creatures.

3843. *The wheat midge (Cecidomyia tritici), millions and millions of which infest every wheat-field, is hardly known by farmers to do them any wrong; and yet, on an average, it destroys one-twentieth of a crop, and may possibly destroy a great deal more. It appears in June, up to which time its chrysalis lies amongst the chaff of the corn. When the corn is ripe, the pupa of the midge are driven forward with the chaff from the winnowing machine, and fall before it within the space of about three yards. As wheat is always averted before it is given to horses, and the pump passes through the sieve with the dust, it occurred to Professor Henslow that if a wire gauge sieve were placed before the winnowing machine in a sloping position, so as to allow the chaff to fall upon it, and then roll from it the pump would pass through, and might be taken with the dust in a tray placed below the sieve. (Gard. Chron. 1841. p. 5. 32. 599. 815.) The pump dropped through to which salt and sand might be applied, or contain a liquid mixture of vinegar and spirits of wine so as to cause the water to bear an egg: steep the corn twelve hours, and afterwards dry it with slaked lime, or dry turf ashes, and sow it as soon as possible. (Gard. Chron. 1841. p. 69.)

3845. *Smut* effectually cured by searing in boiling water for a few seconds, and then dipping in cold water; or then that the water be kept boiling and the grain be rapidly shaken in the water as soon as completely wetted. (J. Ellis, Esq. of Burntwood in Kent, at the February Meeting of the English Agricultural Society.)

3846. *Professor Henslow found, that steeping in sulphur of copper effectively prevented disease, while it did not affect germination. (Gard. Chron. 1841. p. 815.)

3847.—*4999. The advantages of cutting corn crops before they are dead ripe, that is, when the straw immediately below the ear is just beginning to turn yellow, are thus described by Mr. Bannning:- An inspection of the grain, by exposing it to the weather, improved quality of straw, and an extension of the harvesting season. To these may be added, greater security against the effects of wind and rain, either as affects the shedding, discoloration, or germinating of the grain. The colour of grain which is cut at the pitch of ripe, universally of an opalescent whitish hue, while that which was cut before it was dead ripe is transparent, and tinged with brown. The latter description of sample bears the highest price in most British markets. (Brit. Farm. Mag., vol. v. p. 23.)

3848. *The period at which corn crops ought to be reaped is best determined by examining the upper grains of the spikes. The cereal grasses, like all monocotyledonous plants, ripen their seeds on the upper extremity of their flowers, or even in the upper part of their seed-vessels, in the case of plants with pods containing many seeds: whereas dicotyledonous plants ripen their seeds equally throughout the seed-
vessel, and in general rather ripen them first at the lower end than at the upper end. When the uppermost grain of a spike of corn has dropped out, the stalk may be considered as having stood rather too long, and the reaping point to be that when the uppermost grain is firm and plump. On the whole, the most approved practice of British farmers is in the earlier state of ripeness than they have hitherto been accustomed. (Quart. Journ. Agr., iv. p. 501.)

Cutting grain crops with a common scythe has been generally practised in Aberdeenshire since 1818. The crop is grown in this country are chiefly the common grass and clover scythe, for cutting heavy or lodged grain crops; but for light standing crops, a very simple addition is found of advantage. This consists of a small rod or shoot, nearly an inch in diameter, of green willow, or rowan (mountain ash), or some other hard wood. It has its thick end twisted into the small iron rod, which aids in attaching the blade of the scythe to its handle, named provincially the grass-nail. Its small end passes over the upper side of the blade as far as the back, where it is bent upwards in an easy curve, and is brought backward, and tied with several rounds of strong twine. The last round of twine is doubled upon itself about fifteen times and tied, and the scythe is then laid away from the standing corn. Every mower is attended by a gatherer, and, as the gathering is the part of the work that women can best perform, the gatherers are generally women. In gathering the wheat they have first to cut the standing corn, the root end of the stems pointing partly backwards and partly forwards towards the um field of the stock. They gatherer places herself at the root end of the stems, so as to be able to strop forward nearly in the line in which they are laid; she places the corn on the rear over that which is more forward, stepping at the same time towards the right hand herself, she gathers into one heap what she deems sufficient for a sheaf, and, having carefully separated it with her right hand from the forward part of the swath, then makes a band, in the ordinary way, of a part of the gathered heap, and lays the heap upon it. A woman binder also eludes to everyone. It is able to bind up all the sheaves cut by one scythe, and also to set them up in shocks; but there is no novelty in his operations. The gatherer and binder could generally, after a skilful mower, gather up all the corn sufficiently clean; but their labour would be greatly impeded, so that they could not keep with the scythe, were the closest gathering strictly enforced. That is, therefore, dispensed with; and a raker, generally a woman, follows the other operators, to collect the straggling ears and straws. (Highland Soc. Trans., vol. x. p. 189.) The Rev. James Parfarrhion, speaking of this mode of reaping, says, "I approve practics of agricultural labour, not excepting the one drawn by ten oxen, or of the threshing-machine for the flail, has a more valuable advance been made within our memory, from an old and inferior system to a new and better one, than in the adoption of the scythe. The reapers are the most industrious and agreeable workmen in the world. It is double the work to hinder them, and to double the work to hinder the sickle. It is also better performed; because the straw is cut off more closely to the ground, and consequently a better provision is made for cattle fodder during the winter, and for a large quantity of manure."

The scythe has not been used on country places, where the grain is overgrown with grass, as it would be impossible to make the grain stand up enough to permit cutting with the scythe. The most pleasing advantage is the total change of the character of the labour, as it affects the larger part of the workpeople. The mowers, gatherers, and rakers deem their work delightful in comparison with the labour of the scythe. (Quart. Journ., iv. 363.)

The scythe for reaping corn (fig. 1779.) should have its blade (a) of the best steel, four feet long, strengthened by a plate of iron along the back (b). The handle should be straight, because that gives the greatest command over the scythe. A wedge-shaped blade of improper thickness, with a slight curve at the root end, for receiving the scythe in a proper position, makes the best handle to a scythe; the scythe being formed by the side of the sandstone, to what the edge of the scythe, are hooked on to the handle at c, near its upper extremity. There should be a cradle (d), consisting of three long teeth fastened to an upright stem (e), formed of the wood of the horse chestnut. The upper tooth should be a little more than two feet in length, and the two under ones should be the first three inches, and the second six. The cradle is driven into a socket of iron. The height of the cradle is about thirteen inches; the left-hand handle (f) is straight, and the right-hand handle (g) is curved. For the construction of the scythe, further details will be found in the Quart. Journ. of Agr., from which our figure is taken; but the above outline will suffice for any one who can construct a common scythe.

Corn of every description may be reaped with the scythe. Oats make the most perfect work, with the greatest ease to all the labourers. Barley, with new grass, is not difficult to cut with the scythe, but the chalymp juice from the barley straw lubricates the scythe with a viscid coating like varnish, which must be rubbed off frequently with the whetstone. The binders have always hard and easy work among barley, because it is generally laid in swath when mown. The walkers and binders also have a hard time among wheat, the stuff being most powerful men to continue a length of time at the work without making use of a pail, and, of course, of diminishing the fatigue. For example: when a field of wheat and a field of oats are nearly ready for reaping, it is an excelleat arrangement to reap the oats in the dewy mornings, before breakfast, and the wheat in the afternoon. When the wheat are reaped dry, but have afterwards been soaked with rain, will be longer before they are ready for the stacks than oats that have been reaped in a damp state. It is a still more remarkable fact, that damp oats remain longer dry for the stacks than when reaped dry. Not so with barley. Shocks of oats which are reaped dry, but have afterwards been soaked with rain, will be longer before they are ready for the stacks than oats that have been reaped in a damp state. It is a still more remarkable fact, that damp oats remain longer dry for the stacks than when reaped dry. Not so with barley. Shocks of oats which are reaped with the scythe will be quite ready for the stack in eight days, whereas oats reaped with the sickle require at least a fortnight. Shocks that have been reaped with the scythe will keep off much more rain than those reaped with the sickle. It is grown extensively in Egypt and Barbary, in the Caracas, and in Cuba, in
places little elevated above the sea. Hence it may grow in the West Indies. The varieties cultivated in warm climates accommodate themselves to them. (Gard. Chron. 1841, p. 431.)

3534. Cone wheat, a variety of Triticum turgidum, has been found by Mr. Gorrie to be but little injured by the wheat-fly, as this insect appears in the fly state much sooner than the wheat blossom burns from the heat of the summer. The grains of this variety vary in size from seventy to ninety grains, which is double the common of grain. Triticum hybrideum. It ripens a week after the red wheat, and, when standing, is from a foot to eighteen inches taller than the red variety itself. (Quart. Journ. Agric. vol. III, p. 641.)

3535. Danzig creeping wheat is a variety cultivated on the borders of Scotland, which possesses the property of tillering, or throwing tap-shoots from the root in the autumn, in a remarkable degree. It originates in Danzig. (Q. Art. Journ. Agric. vol. V, pt. I.)

Mr. Hannam shows that by wheat being cut raw we have a gain of 15½ per cent., compared with wheat cut ripe, of four, upon equal measures of land; and again in the weight of straw, of 14 per cent.; advantages which afford a clear gain of 52½ lbs. of flour upon every quarter of wheat, in the value of every quarter of wheat. A gain of 7½. 6d. in the value of every quarter of wheat, and the straw producing it. A gain of 7½. 6d. upon every acre producing 28 bushels, and of 11. 8s. 2d. upon every acre producing 30 bushels. (G. J. A., vol. xii, p. 178.)

3537. For the purpose of plowing horses, and rye is somewhat extensively cultivated about Newmarket for the sake of obtaining the straw for the livelier stables. (J. D.)

3538. Naked barley (Hordeum distichum var. nudum Metz.), strongly recommended in preference to other varieties, will produce better, per bushel; flour whiter and sweeter than common barley flour; absorbs more water, and makes better bread; malts in seven days less time than common barley; will raise the land as well as four of other barley, with other excellent qualities. (G. J. A., vol. IV, p. 180.)

3539. The Hopewell set in an agricultural variety brought into notice by Mr. Sheriff in 1824. It is chiefly remarkable for its long reedy straw, which, in a crop of twenty acres in East Lothian, has averaged six feet in length, while the grass is thin in the husk, and nearly as short and plump as the grains of the potatoes of the large potatoes of Highbury. (G. J. A., vol. II, p. 595.)

3540. The value of crops of Swedish turnips, potatoes, and mangold werzel as food for cattle is not materially different, provided the crops are alike good of their kind. This is the opinion formed by an experienced farmer and agriculturist after having made a number of experiments to determine the value of these roots. (Highland Soc. Trans., vol. I. p. 273.)

3541. The Indian potato is a variety of Ostrogoth, which is cultivated extensively both in Europe and North America for its large produce, chiefly applied for feeding cattle. Mr. Buel of Albany had nine bushels as the produce of twelve lbs. (Gard. Mag. 1841, p. 98.)

3542. The pine-apple potato keeps sound and well flavoured till June.

3543. The King Castle kidney potato is large, very mealy, and superb in flavour to any other kidney. The potatoes, which weigh sixty pounds, are made into a quantity of flour remarkably full, and hence there is little waste in paring or peeling them. They have been grown for twenty years in the garden at Knock Castle, near Horam, Sussex, without degenerating in the slightest degree. (G. M. 1840, p. 102.)

3544. The best early and late potatoes. The Mandy, a round white potato of moderate and equal size, is one of the best early sorts: and the breadfruit, a rather large round white potato, a good bearer and a good keeper, is one of the best late sorts. (G. C. 1842, p. 97.)

3545. Comparative merit of different varieties of potatoes. Experiments with a view to determine the comparative merit of different varieties of potatoes, are at the conclusion that the bampers and the crops are excellent varieties to grow for cattle, because they cover the ground well, do not curl, and produce great weights. In autumn the white and blue Dons are excellent for family use, and in spring the old rough black and Irish are the most productive, and those that come first that come into use, and next Dugdock's black early, and the Flamingo or red early. (Trans. H. S., vol. xli, p. 83.)

3546. Soil for potato. In the peninsula of Kintyre, the soil is calcareous clay, in which there is found gypsum, an excellent addition to the potato; and there are no weeds to the potato; and the potato crops far surpass any he had elsewhere seen, either in Scotland or Ireland. (Brit. Farm Mag., vol. vii, p. 479.)

3547. Comparative produce of different modes of preparing the sets, and planting potatoes. The following interesting experiments were made by the Messrs. Drummond of Stirling, with the Irish blue potato, on the same piece of ground, and under similar circumstances. The space which each experiment occupied was forty square yards, which were divided and dunged at the rate of thirty tons the imperial acre. They were sown 1st October 1832, and harvested 15th October 1833.

3548. The first plot was planted on the plan recommended by Mr. Knight, Pres. Hort. Soc. The tubers were whole, weighing half a pound each, and were planted at the distance of six inches in the row, and the rows four feet apart, and lying north and south: forty square yards required nine pounds of sets, and produced 364 pounds of potatoes, being, per acre, 156 bushels of sets, and 550 bushels of produce; net increase, 414 bushels.

3549. The second plot was also planted with similar tubers to the last, at nine inches apart. The seed required was sixty pounds; the produce, 326 pounds; being, per acre, ninety-one bushels of seed, and 453 bushels of crop; net increase, 402 bushels.
of potatoes, and the crops contained a great proportion of small ones.

The third plot was planted the same as the last, but the sets were cut of the common size. The seed required weighed only six pounds, the produce, 276 pounds; being, per acre, nine bushels of seed, and 40 bushels. The plants in this plot grew fast in the autumn, and produced by much the largest potatoes; but they did not ripen well.

The fourth plot was planted with sets cut of the common size. The seed required weighed twelve pounds, the produce, 376 pounds; being, per acre, nine bushels of seed, and 550 bushels. The potatoes in the produce of this last lot were the most equal sized.

The result of these experiments (which were conducted with great care) is entirely contrary to Mr. Knight's theory, and consequent practice. (Quart. Journ. Agr., vol. iv. p. 411.) In the Transactions of the Horticultural Society, second series, vol. i. p. 445, Mr. H.177. Drummendall, however, gives a number of experiments made with the greatest care and accuracy, under the direction of Professor Lindley, in the garden of the Horticultural Society, the result of which is confirmable to that observed by Mr. Knight in his experiments in Ross-shire, and I think the produce of the experiments of the largest kind in Ross-shire, and found the produce decidedly better from sets than from whole potatoes. (See Gard. Mag., vol. x. p. 433. 435, and p. 499.)

The depth at which the potato should be planted in warm dry land 9 inches are not too deep; in cold stiff soil, 4 inches would be better; 6 inches is a good depth for average land. Certain experiments conducted in the Hort. Soc. garden, gave the following results: 3 inches deep gave 13 tons; 4 inches, 14 tons; 6 inches, 14½ tons; and 9 inches, 13 tons. At so great a depth as nine inches there is no danger of any of the tubers becoming damaged, and the sets can be safely inserted, the better, for the following reason; potatoes are formed on underground branches; the deeper the set, the more branches will be formed before the shoots emerge from the soil, and less than unearnt potatoes. (G. J. A. vol. v. p. 191.) A good deal depends on the variety of the potato, the stools of some, such as the Irish potato, have a tendency to rise out of the soil.

The weissness of earthing up potatoes has been pointed out by Mr. Hay ward, and independent of the effect of earthing up and in destroying the rows, in destroying weeds and loosening the soil, we should think his practice the best. He says, that a farmer who simply hoed the soil between the rows of potatoes in one of his fields, had a much larger crop than he had in an adjoining field, which was hoed in the same manner, and in which the leaves of the potatoes were thrown up and earthed up. He considers the surface of the soil will produce a greater number of tubers than one planted at the depth of a foot. "I have no doubt," says Mr. Hay ward, "if potatoes are planted shallow, and placed wide enough apart to admit a little of the topi or top, that they will not produce such a large number of large potatoes, as when they were then thrown over five or six inches thick, so as to form a flat surface, that it would increase the crop. But this is a very different operation from that which I object to." (Gard. Mag., vol. ix. p. 132.)

Benefit resulting from the removal of potato blossoms. By a well-conducted experiment on a field of two acres, for which the honorary silver medal of the Highland Society was given, it appears, that one third part of the field, being those drills from which the blossoms were blucked in the bud, produced thirty bushels, two bunches. One third part from which the blossoms were plucked when in full flower produced twenty-seven bushels, three bunches; and one third part, being those drills on which the plants were allowed to ripen their seed, produced twenty-six bushels. The difference here, in favour of plucking off the blossoms as soon as they appear, instead of allowing them to remain and ripen their seeds, is very striking. (Highland Society, 1834.)

Potatoes should never be covered with straw excepting on the outside of the earth, for straw soon decays, and communicates a bad flavour to the potato. Quantity of sets to an acre 21 bushels, the rows 3 ft. apart, and the set 6 in. distant in the rows.

Precisely of potatoes, Mr. Knight raised 34 tons and Mr. Parker 32 tons per acre; a ton is 40 bushels. (G. C. 1841, p. 247.)

Potatoes may be preserved by being rapped or ground to a pulp, afterwards pressed into dry powder, or any other powerful press, and dried dried like chesse. Potato cakes of this sort have been found to keep for years perfectly sweet; and, as a great deal of nutriment is thus put into very little bulk, it is thought that some ships bound for long voyages might find it advantageous to lay in a supply of potato flour. (Quart. Journ. Agr., vol. iv. p. 414.)

Potato flour was shown at Messrs. Drummend's exhibition at Stirling in 1832, which was thirty-eight years old. It was made from damaged potatoes, which, it seems, answer as well as sound ones, and was in the finest condition. (Quart. Journ. Agr., vol. iv. p. 414.)

Potato flour forms a rich and excellent manure for wheat, at the rate of four acres of grain to one of potato, ploughed in green immediately before sowing the wheat. It is 'ound decidedly superior to stable-yard dung. The mode of preparing it is simply to pull up the stems, and to avoid bruising them with it, however well they may be ground. Good beer can be produced from potatoes by grating them to a pulp, mixing it well with boiling water, and then adding ground barley malt. The liquor, being drawn off, is to be hopped in the
usual way, yeast added, and fermentation induced. The liquor thus produced, after being bottled, was found greatly to resemble the Paris beer. (Don. Econ. in Larrey’s Cyclopædia.)

3830. Beer may be made from parsnips in a similar manner to that from potatoes.

3831—3834. The distillation of spirit from potatoes is thus practised in Peru.—The potatoes are boiled by means of a steaming apparatus; and, where the apparatus is good, will be prepared sufficiently in ten minutes. As soon as they are in a proper state, they must be bruised when at as high a degree of temperature as possible, and then thrown, for the purpose of fermentation, into a tub or other receptacle containing, for every 1000 pounds of potatoes, 416 pounds of cold water: the temperature of which, however, should not be below 140° of Reaumur (53° of Fahrenheit). The whole must then be covered up, and allowed to ferment, which will take place in the ordinary manner mentioned; and this proportion, with the 416 pounds of water, will be quite sufficient to produce a mass, of which the consistency will be that of pap or curdled milk, and the temperature from 45° to 50° Reaum. (14° to 14° Fahr.) There are then taken 313 pounds of the malt of barley, which is steeped in 236 pounds of water that has been previously heated to the height of 5° Reaum. (23° Fahr.). The whole is then added to the mass, and allowed to remain until it shall have cooled to the temperature of 22° of Reaum. (81° Fahr.). There are then added 22 pounds of yeast, which is mixed by being actively stirred, and the whole is then well covered and allowed to remain. When the mass of fermenting potatoes has acquired the temperature of 38° of Reaum. (111° Fahr.), the fermentation is stopped by adding 416 pounds of cold water, and the whole is well stirred together. This mass having fallen to the temperature of 25° Reaum. (88° Fahr.), the prepared mass, which has already begun to ferment, is added; the whole is again well stirred together, the vessel very lightly covered, and the fermentation allowed to proceed. This latter operation takes place very regularly, and terminates in from forty-eight to sixty hours. The fermented mass assumes a spirituous odour, and furnishes, on distillation, so abundant a quantity of spirit, that for every 1000 pounds of potatoes, there are obtained eight gallons of spirituous mass, which, when added to the mass of fermenting potatoes, gives the liquor at the proper temperature, which is then placed in a still, and the spirit of the liquor is run off in the usual manner; and, when the spirit is matured, it is removed from the still, and placed in bottles for future use. The temperature of the liquor at this stage is nearly 88° Fahr.

3835. Mincing potatoes, and mixing them with the liquor, is a way, not recommended to farmers. The liquor should be run into a great chaff, completely prevents the fermentation of the potatoes in the paunch from injuring the cattle. They eat up the prepared mess with relish, are soon satiated, and then lie down with ease and comfort, and of course fatten rapidly.” (Q. J. Agr., vol. vii. p. 244.)

3839—3869. Frozen potatoes. When frozen potatoes are thawed, they frequently do not give a fourth part of the starch which they give before being frozen. The cause of this, it appears, is, that the starch, belonging to each individual particle of the parenchyma of the potato, is, in the case of potatoes not frozen, set free by the operation of theras or greater rasping, and brought down for starch. When the potato has been frozen, however, and is afterwards thawed, the cells are no longer firmly fixed in the fibrous matter of the potato, and the grater has no longer any power to tear them to pieces; every one knows that the most seedy part of a potato is immediately within the skin; and M. Payen has discovered that by far the greater number of cells of starch are in that part of the tuber, and that there are comparatively few towards its centre. M. Payen has also discovered that the freezing of a potato before it is parboiled, causes the cells within which the starch is found in the frozen potatoes. Before the potato is frozen, the bitter principle, being contained in the skin, is readily removed by paring or peeling; but, when the structure of the parenchyma of the potato is altered by freezing and thawing, the bitter matter is communicated to the adjoining parts of the potato, in consequence of their comparatively fluid state. The inhabitants of Peru dry their frozen potatoes, and thus preserve them for food for an indefinite length of time. (G. M. 1839, p. 136.)

3894—3077. Dale’s hybrid turnip was originated, about 1828, by Mr. Robert Dale, of Liberton West, near Edinburgh. It is tankard-shaped, and resembles the Swedish or yellow turnip in colour. It is equal in size to the white globe, superior in size to most other varieties, weier, yellow, and black. It is, however, a much inferior food than the white or yellow; and, in order to increase the acidity and the size of the globes, they are usually planted with a smaller proportion of potatoes, and are found to produce a greater weight in a given space, and at a given expense of manure, than any other turnip hitherto introduced. It is not so hardy as the Swedish, and it runs rather sooner in the spring; but, with these exceptions, it is the best of all field turnips. (Quart. Jour. Agr., vol. iii. p. 578.)

3895—3040. The most economical mode of dividing a field of turnips which is to be eaten off with sheep. I have this year two pieces of turnips, of ten acres each, nearly square, which I intend to divide by hurdles into eight divisions each, for eating off by sheep; the ground by sheep and young cattle: now it is plain that if I divide them straight across the field, from hedge to hedge, I shall have seven settings of hurdles, of 220 yards in length, in each field, making in the whole a length of 3080 yards for setting hurdles at different times.

To save labour, I therefore adopt the method explained in the annexed diagram, fig. 1180. Suppose the figure, A, B, C, D, a square field of ten acres, then a b will be the first setting of hurdles, c d the second, b c the third, c f the fourth, b f the fifth, h t the sixth, b k the seventh, and l m the eighth; in the whole, eight settings of 110 yards each, or 880 yards; in both pieces 1760 yards, or one mile; and the turnips will be eaten in rotation, as the plots of ground are numbered.

s:t%._ sil.'t. The taste of turnips in milk, butter, and beef, it is said, may be prevented by the following
meant :— " Never allow the cow to taste Of t In roots within six or right hours of milking, but feed her
immediately after each milking; and do not give her ativ more of the roots at a time than she will eat
in two or three hours, and In- careful that she dors not gel any mole till after she is milked again.
By
this method cows maybe fed on rutabaga or other turnips, and no person will be able to discover the
taste in the butter or milk.
Upon tin- same principle, those who wish to teed their rattle on turnips
may do so without any danger of affecting the taste of the beef, provided they will omit feeding with this
kind of food two or three days previous to the killing. Cases have occurred where the beef was rendered
unlit to eat, on account of the animals eating a few turnip-tops or cabbage leaves before being slaughtered.
The difficulty may be obviated as mentioned above."
5480. Storing turnips. By experiment it was found that raising them in stacks above the surface by means of wattled stakes to prevent them from spreading out, and when the stack is as high as it
will stand, thatching them is superior in every point of view to burying them in the soil in the manner of
potatoes. {.Jour. A. E n vol.11, p. 228.)
5432. Fly on turnips.
The following mode of prevention has been resorted to with success at
(ireen llammerton, Yorkshire. A board, about eighteen inches in breadth, and sufficiently long to cover
four ridges of turnips, was made to run upon wheels, high enough to allow the board to pass over the
turnips without touching the tops of them.
The lower side of this board was painted with white paint,
which the men provided themselves with, and took into the field, and during the night (at which time the
By is more injurious and destructive than during the day) the instrument was wheeled from one end of
the in Id to the other. The insects, on being disturbed, of course immediately fly or jump up, and stick
to the paint; and at the end of every set of ridges the board was almost covered with them.
(Leeds
8399—5444. The while or Belgian carrot, produced on Lord Ducie's farm at Whitfield, at the rate of
20 tons 3 cwt. per acre. The soil is a deep sandy loam, belonging to the new red sandstone formation.
•' The
seed was sown in the second week in April, on land which had been ploughed 10 inches deep. It
was sown on the flat, in rows 18 inches apart, by the common Suffolk drill. The seed had been mingled
with damp sand for several days previous, as well to sprout it partially, as to render it capable of being
(

drilled, as carrot-seed clings so much together.
They are thinned out when a fortnight old, to intervals
of 6 inches in the row, and two horse-hoeings, with a hand-hoeing whenever the weeds made their appearance, was all the cultivation they received. The result is a crop, not only much more valuable per
ton than any other green crop we have, but also heavier per acre, and raised at an expense less by at
(Journ. A. E., vol. ii. p. 40.)
least one-half than that attending the cultivation of the turnip."
8400. The white carrot. The produce with Sir C. M. Burrell in Sussex was upwards of 1,300 bushels
per acre, after separating the green tops.
Some of the roots had penetrated as deep as 3 feet 51 inches,
so that the white carrot cannot be a very scourging crop. The soil was loamy and well and deeply
drained, and subsoil ploughed, but not manured. (B. F. M., n. s., vol. iv. p.4tii>.)
S40I
5453. Carrot seed. Messrs. Drummond, the eminent seedsmen of Stirling, state that the carrot

—

crop in the Held may almost always be insured, other circumstances being favourable, by bringing the
seed to the point of vegetating before sowing. This is done by mixing it with sand or earth, kept moist,
ami turned occasionally for several days. They also recommend some nourishing compost to be placed
under the seed in the drills, or sown along with it. They have made an experiment to prove that carrots
may be grown to great advantage in peaty soil, and that they may be even grown in old worn-out garden
soil by mixing peat and dung together, and putting the compost thus formed in a gutter made by a wedgeshaped dibble, six inches wide at top, six or eight inches long, and at least a foot deep the seed being
sown immediately above the compost. (Quart. Jour, of Agr., vol. iv. p. 410.)
8402. 5471
The parsnep is superior to all other roots lor fattening hogs ; but they must be given raw,
for the boiling of the root renders the bacon flabby. Parsneps will fatten a hog in six weeks, more especially
ii snur milk is given with them.
The roots are never to be washed, because it is found that washed roots
are found to surfeit both hogs and cattle. (G. C. 1842. p. 837.)

< ookery.
like those of the skirret or scorzonera.
s|n7.' i.upi/iu.s po/yphy/lus has been tried as a forage plant by the Earl of Mansfield, and found valuable in good sandy loams, but it is thought inferior in nutritive properties to the lucent.
8408.—5522. 'Vrifblium ilegant D.Don., T. hybridum Bon Jardinier, the elegant hybrid or Alsike
clover, apparently a gigantic variety of the common white clover, has been cultivated in Sweden for upward) oifortj years, though only lately brought into notice by M. Vilmorin. It product's trailing shoots
live in -i\ feet iii length, is remarkably hardy, and prefers strong moist soil.
believe it to be the same
plant which we collected in Poland in 1813, and of which we exhibited specimens at the Linnaan Society
about the end of the following year. In England it is now being cultivated by Mr. W. Taylor. F.L.S., who
conceives a very high opinion of its value to the agriculturist. It does not suffer, he says, from the
severest frost, its growth being merely suspended, while its foliage is not injured ; it may be readily propagated on a large sr.de by division of the root, and it flourishes in inferior soil.
5527. Trifblium incaruiilum is considered in Italy as the earliest of clovers ; as particularlyB409
calculated for dry soils, and as preferring the mountain to the plain. It is an annual, and succeeds best
when sown in the autumn, after the corn crop has been remo\ ed. (Quart. Jour, of Agr., vol. iii. p. 729.)
7'rifiilium incarnation is found of great value in tilling up blanks in fields of common clover being sown
immediately after carrying the corn crop.
8410. Trifolinm gig'aiitium, the Affghan clover, thrives in England during summer, but is too tetn'er

productive of forage; but though many attempts have been made to bring the seeds to Europe in a live state, the attempt has not yet been attended with success. (G. C. 1842, p. 335.)

4834. 5649. Gorse, instead of being bruised as formerly before being given to horses or cattle, is now cut by machines like those in use for cutting hay and straw. It is found that both horses and cattle feed with great avidity and regularity on this crop, which is clearly shown by the following experiment. A sheep was placed in a field of gorse or blackthorn, and in the course of the time the sheep completely approached a pulp, by bruising or crushing. In this state also it is apt to become sour in the summer season, in which state it is rejected by all animals. (Brit. F. M., N. S., vol. iv. p. 350.)

4835. It is the opinion of Professor Kinneir, that, on comparing different species of grass, he has long been of opinion that permanent pasture, instead of being a good thing, is a bad thing. After reviewing his experience during several years, and strongly recommending thorough under-draining, deep ploughing, and manuring, he concludes thus:—"I maintain that, except a few favoured spots, such as level meadows near the sea or in old fields, and that it may be true, in the country where the top soil is clay and where the duration of the pasture is short, or for hay, but not where the grass is to be reseeded, that without cropping, grass cannot be made to continue at the maximum point of verdure and utility. Lastly, I maintain, no land, under any circumstances, ought to be cut in hay, if intended to remain some years in its natural state; and ought to be directly ploughed, and again put through the rotation." (Quart. Jour. Agr., vol. iv. p. 790.)

4836. 5647. The great object of mixing different grass and herbage seeds together, is to stock the surface of the soil at once so thickly with useful plants as to prevent weeds from rising up through them. Experience has shown that a mixture of spring-grasses and clover with a greater number are made use of: and the reason appears to be found in the diversity of soils and situations. In general, the richer the soil the smaller will be the number of species of grass and clover that can be successfully sown; and to this end the mixture of grasses and clover should be so composed as to provide a certain quantity of seed to cover the ground, that quantity should be composed of the best kinds. One reason for sowing a number of kinds is, that more plants will thrive closely together of different sorts than of the same sort. Allowing this to be the fact, there is still no necessity for incurring the trouble and expense of sowing worthless kinds, when a variety of them will grow naturally out of the soil to form a thick sward. Should the different kinds arrive successively at their greatest vigour, seeds of the best sorts can be selected on account of their coming to maturity at the different seasons when pasture is in general use. (G. C. 1841, p. 27.)

4837. 5650. Italian rye grass, Mr. Lawson says, is commonly used in the British Islands, where it grows only 1 foot high, and, like other Cârnees, is of great value for cattle. (Brit. F. M., vol. iv. p. 17.)

4838. 5651. The Italian rye grass, Mr. Lawson found to be the same variety as Stickney's rye grass. It is generally sown in small quantities along with Trifolium incarnatum, which keeps pace with it in early and vigorous vegetation.

4839. 5652. Pâne nemorali var. incarnatum, the Hudson's Bay meadow grass, has been brought into notice by Mr. Bischof. Its value arises from a property which it possesses, and which is common to no other grass cultivated in Scotland, viz., that of the flower stem, after being cropped, reproducing shoots from the stem as well as from the root: in consequence of which it grows throughout the whole year, particularly in the latter part of summer and autumn. A specimen grown off cold damp land, measures 50 inches to 20 inches above the ground length. (G. M. 1841, p. 18.)

4840. 5653. Brîmus praeclus L., B. erectus Sinclair, is strongly recommended by M. Vilmorin for poor soils liable to be burnt up with drought. Sheep, he says, are remarkably fond of it. (G. M. 1841, p. 467.)

4841. The common rye grass. (Highland Soc. Trans., vol. iv. p. 28.)

4842. 5671. Number of kinds of grasses required in laying down permanent pasture. A judicious writer in the Quart. Jour. of Agr. is of opinion, that more of these grasses are brought into notice than their good properties will warrant. Independently of perennial clover, every good clover and white clover, will do well when sown a large patch, and consequently of every permanent pasture, perhaps five or six of the others are all that are worth cultivation. It is true, many worthless grasses will grow up among our most carefully laid down pastures, and they do not assist in thickening the sward. But this is surely no adequate reason to sow such grasses in a large proportion of the mixture, instead of selecting the best kinds. It is not merely a question of species, but of varieties. A good mixture consists of species, whose total number is four to seven, and each of them distinguished by a degree of success which has been acknowledged by the first agriculturists in Scotland to be pre-eminently great. After giving a short description of thirty species or varieties of proper grasses, and eleven herbage plants, of which he has seeds for sale, he enumerates the quality of each kind, under the name of comon, but which he says may be disadvantageously introduced into cultivation, as well as being useful, the kind, if their seeds can be obtained. These are, Lótus major, Vicia Crêna, F. sépinium, and T. sylvatica, Lâthvus pratensis, and Trîfolium medium.

4843. The sowing of grasses and herbage seeds. Mr. Lawson, in the Quart. Jour. of Agr., takes great pains to point out the general practice of sowing the grasses by measure, and the clovers by weight, is strongly recommended by Mr. Lawson. "For, although in grass seeds the greater weight of one variety is no criterion of its superiority over another variety of the same weight, yet a greater weight of any variety is no evidence of the same variety, as the weight of any plant is not to be measured accurately by the light, and consequently, the greatest number of seeds is obtained by adhering to a given weight; and hence there is the chance of nearly an equal number of plants springing up as when the seeds are plump and heavy. But a given weight of measure of seeds does not indicate the relative bulk and specific number of plants that will spring up; because there is both a difference in the relative bulk and specific
gravity of seeds, and there is also a difference in the number of seeds that grow from a given quantity.” (p. 719.)

8425. The weight of the seeds of grasses, per imperial bushel, is next given by Mr. Lawson; and the differences between the seeds of different species in this respect is most remarkable. Of thirty species, the heaviest appears to be the common perennial rye grass, a bushel of which weighs from eighteen to thirty pounds, and the next heaviest, and the only two species to be the clover, weighing sixty and three-quarters; and the next lightest is that of Avena [Trisetum] flavidus, a bushel of which weighs only five pounds, and the next lightest is the meadow fox-tail grass, which weighs five pounds and a quarter. Anthoxanthum odoratum and Alnuscescens geniculatus weigh each six pounds; Araficus, six pounds and a quarter; Poa hagei, seven pounds and a half; Festuca arenaria and Frasica durilica, each nine pounds and a half; and the remaining species weigh from ten to sixteen pounds. Rye weighs sixty-two pounds the bushel.

8426. The weights of clover and other herbaceous plants are much less various. Burnet weighs twenty-four pounds and a half; saffron weighs twenty-six pounds; Achillea Millefolium, twenty-eight pounds and a quarter; wilwort, fifty-one pounds and a half; Medicago lupulina (the nonsuch of English farmers, and the most improved of the clovers) weighs sixty-three pounds and three-quarters; and the different species of clover (Trifolium), from sixty-two to sixty-five pounds.

8427. With reference to the culture of grasses in Britain, Mr. Lawson observes that, wherever land produces the cereal grains and other cultivated plants, the pasture and herbage grasses will grow with vigour. Pasts of this kind, he observes, are improved by different kinds of soils, and more especially with relation to their state of dryness or moisture. As a convenient arrangement for practical purposes, he classes all soils under light, medium, and heavy; and he has composed twelve different tables, each containing the quantity of grass seeds, per Scotch acre, for these three divisions of soil. Whether in Britain or America, wishes to sow grasses on a large scale, will find it worth their while to correspond with Mr. Lawson, with reference to the subject of these tables, because every year he is adding to his experience, and in all probability improving the selection. We shall, therefore, not copy them into our pages in detail, but merely give their titles with a few remarks, chiefly with a view of showing how much greater the number of species is which Mr. Lawson recommends than what is commonly sown, and yet how much smaller is the quantity of seed per acre.

8428. Grasses and herbage plants for alternate husbandry. For one year's hay, twenty-two pounds of annual rye grass, ten pounds of red and two pounds of white clover. For one year's hay and one year's pasture, eight pounds of annual and eighteen pounds of perennial rye grass; three pounds of Phleum pratense, for one year's hay; and two pounds of white clover. For one year's hay and two years' pasture, twenty-eight pounds of perennial rye grass, two pounds of Phleum pratense, two pounds of red, six pounds of white, two pounds of cow clover, and two pounds of nonsuch. These proportions are for soils suited for the turnip husbandry; in heavy soils, from two to four pounds of clovers, and perhaps a quarter of the year's grass.

8429. Grasses and herbage plants for permanent pasture. Of proper grasses, seven species are employed; of proper clovers, three species, and also the nonsuch. The proportions are given for laying down without11, when the clover is also employed; and it is thought that in the latter case the quantity required is not much above half what it is in the former. Without a crop, seventy-five pounds are required for a light soil, and eighty-two for a heavy soil; while with a crop, forty-one pounds and a half in the one case, and forty-five in the other, may be required.

8430. Grasses, &c., for permanent pasture in ornamental parks. Of proper grasses, fourteen species are employed, besides the clovers mentioned in the preceding paragraph. It is added, that Achillea Millefolium may be added in dry soils; saffron in dry calcareous soils; wild endive in heavy soils; and from among the grasses are sheep and cattle kept on ten lands where the latter case the quantity amounted 500 feet and upwards above the level of the sea, sheep’s and cattle, and the two allied species, and Poa glauca, may be added, at the rate of two pounds each.

8431. Grasses for improved deep peaty ground intended to lie in grass. Perennial rye grass, ten pounds; Phleum pratense, eight pounds; Poa trivialis, two pounds; Alnuscescens pratensis, two pounds; and Trifolium répens, eight pounds, are recommended, when they are to be sown with a crop; when without a crop, the proportions are, eighteen, twelve, three, and twelve pounds.

8432. Grasses for land in preparation for irrigation. We shall take the liberty, in this case, of copying the table verbatim:

8433. Grasses for lands which are occasionally subject to the overflowing of lakes and rivers, or which are always in a very wet state. These are, Poa aquática, six pounds; Poa fláitians, six pounds; Festuca lúlæca, four pounds; Phleum pratense, six pounds; Alnuscescens geniculatus, six pounds; Agrisitc stolonifera, four pounds.

8434. Grasses for rabbit warrens, or light sandy soils. These are perennial rye-grass, fourteen pounds; Anthoxanthum odoratum, one pound; Festuca durilica, one pound; Festuca ovina, one pound; Festuca pratensis, one pound; Cynosurus cristátus, two pounds; Potérum Sanguinóbra, four pounds; Achillea Millefolium, half a pound; Trifolium répens, six pounds; Trifolium minus vel procumbens,
two pounds; Medicago lupulina, two pounds. If this mixture be sown without a crop, a bushel and a half of rye grass may be sown along with it.

458. For dressing sands, which are to be consolidated, and have a sward produced upon them by sowing. These are, Elymus arenarius, ten pounds, which should be mixed with clay and straw ropes cut into pieces and laid into the sand. When this has been produced, the mixture recommended for rabbit-warrens, or light sandy soils, may be sown.

459. For dry gravelly situations, which resist a sward from all ordinary means. These soils may be sown with a grass of fine, four parts P. flexuosa, one pound; Trifolium minus vel proculum. We repeat our strong recommendation of Mr. Lawson, an agricultural seedsmen, to all persons residing near Edinburgh who have lands to lay down in.

460. We are not averse to recommend Mr. Messrs. D. Drummond of Stirling; Messrs. Dickson and Turnbull of Perth; Messrs. Carrick and Son, and Mr. Gibbs, of London; and M. Vilmorin, of Paris, to all those similarly circumstanced in their respective localities.

461. Mixtures of grasses for the alternate husbandry. From the result of an experiment made by Mr. Shireff (Practical Irrigator and Drainer, p. 292), it appears definitely probable to use a mixture of seeds, even where a single crop of hay, to be succeeded by a year's pasturage, is to be taken. The grass sown were cock's-foot, hard face, cat's-tail, rye grass, and red, white, and yellow clover. The rye grass, being the most nutritious, is the greatest advantage to this mixture in the spring, and retains its vitality unproductive in the summer months. The cock's foot, throughout the season, put forth new leaves with rapidity, when being cut with the scythe, and produced culms to the hay crop only; the clover planted thinly, and also grew rapidly after being cut; the cat's-tail was later in producing flower-stalks, than the divided composite; he again harrows and mows and will eat a part of the cock's-foot and sedge, but, in every instance, it produced numerous culms, white blossomed, at the same time as the red clover; and where a part of the field was four times mown, yielded a rich crop of culms to the hay crop, and of the grass, and of the clover itself which the failure of a crop is rendered next to impossible. It is also found that a mixture of grasses is less injurious to the succeeding corn crop than rye grass only. The family of grasses, Mr. Shiref observes, forms a useful class of machinery in the manufacture of productions for the dairy, the shambles, and the manufacture of bread, and, but in a very few cases, like ad a more richly, more beautifully supplied by nature, the most efficient machinery, must be employed. The husbandman who clothes his fields only with rye grass and clover employs a limited machinery, the former being unproductive in the spring, after which the latter, with the exception of a few species of the clover, is grown for its fibres, differing in their habits of growth and periods of luxuriance, a numerous and powerful machinery is kept successively in full operation.

462. Poa nemoralis was sown by Mr. Taunton to produce a thick sward in plantations where every other grass was killed. He says, its rich nutritive quality, its beautiful and perpetual verdure, and, above all, its quality of flourishing under a dense cover of trees, appear to me to render it peculiarly valuable for the particular purpose of rendering ornamental, and also of turning to a profit, the site of great plantations and the thick groves, which are, usually, in a state of complete nakedness. (Quart. Journ. of Agr., vol. iii. p. 113.)

463. - 568. Irrigating meadows with liquid manure from the common sewers of Edinburgh. This has been found by Mr. Martin, in a meadow on the north side of Edinburgh, near the residence of the Rev. Dr. Stephens (Practical Irrigator and Drainer, p. 76), to be one of the greatest improvements ever made in agriculture. The inhabitants of Edinburgh, however, are of a different opinion, and according to a pamphlet on this subject published in 1836, entitled Papers relating to the Various Effects of the Felis Terregena and the Clove in Edinburgh, it appears that both no horse or other animal will eat a part of the produce of these meadows, either while growing, or when first cut; and the cows when first put to eat it have for some days an absolute loathing, and can hardly be got to feed upon it; but when they do, it is an immense loaf of curd, which is kept of dry grass, and what is called tre (brewers' wash); but whenever the supply of this grass becomes short, they are found to be incapable of digesting the usual fodder of cattle, and completely diseased, and get unfit for any purpose almost. (G. M. 1840, p. 272.)

464. - 5820. To destroy moss in old turf. It is a singular fact, but not generally known to agriculturists, that by merely lifting the turf of an old pasture field that is overrun with moss, and ploughing and loosening the subsoil, and then laying the same turf down again, the whole of the moss will disappear the first season, without applying either water or manure to the surface. (Stephens on Irrigation and Draining, p. 59.)

465. - 5944. Renovating defective meadows. The late Mr. Sinclair, of the New Cross Nursery, had perhaps more experience than any man in the kingdom, and other persons, in a large extent of excellent work the Hortus Graminum Woburnensis, he recommends first ascertaining that the meadow is completely under-drained; then stirring the surface, by harrowing it in all directions; the best harrow for which is unquestionably that of Finlayson. After this he gives a thorough top-dressing of rich finely divided compost; he again harrows and mows and harrows, and then sows from two to six pecks per acre of grass and clover seeds. For a meadow of low rich all soil he employs meadow fox-tail, meadow cat's-tail, meadow fescue, rough-stalk meadow grass, crested dog's-tail grass, sweet-scented vernal grass, and perennial red clover. In two years such a meadow will be thoroughly renovated, and will bear abundant crops of hay.

466. - 5965. New fibre plants. Mr. Taylor of Holbrooke, near Ipswich, sowed five rods of ground with Mistral grass, and having got a good growth, and received from it at the rate of 15 cwt. of satis- able fibre per acre, he had which manufactured into excellent ropes. Malva crispa, M. puruviana, and M. mauritiana also produce fibre which might be applied to the same purpose as that of Sida abitibison; more especially Malva crispa, a very common annual in British gardens. (G. M. 1840, p. 36.) Mr. Wever of Silvex, has been experimenting, for the Continent as an oil plant, and has lately been tried in this country by Mr. W. Taylor, F. L. S., of Holbrooke, near Ipswich, with great success. In 1835, Mr. Taylor obtained upwards of 50 bushels of seed from an acre, which, when sown in a bushel, worth 20s. 6d. per gallon, was purchased by the brewers for 6s. 8d. per gallon.

467. Madia setosa, an annual, a native of Chili, cultivated in gardens as a border flower, has also been grown on a considerable scale in 1830 by Mr. Taylor, who obtained 33 bushels of seed from an acre, which were crushed and produced 250 lbs. of oil, and 410 lbs. of oil-cake. The oil alone was worth 9. (Gard. Mag. 1840, p. 85.)

468. - 6111. "Buckwheat is grown generally into grits by means of handmills, or lever hammers, and is made either coarse or fine. The coarse sort is used for gruel, and the fine sort for cakes and biscuits. In some places the tiger grain, used in the first grinding with the hand, more or less, is added to the finer flour, for baking household bread. It also serves to fatten hogs or poultry in a short time. The principal method to cleanse and separate the husk is, to pour boiling water on a given quantity of cleaned buckwheat, and draw the water through a net, then to press the water, and having first stirred it about well. In a quarter of an hour after, the buckwheat is taken out with the hands, and the water squeezed out. In the summer it is dried in the sunshine, and in winter in a warm warm room, and spread on the floor. As soon as it is quite dry, it is ground in a hand-mill or a dressing-
machine into grits, in which state it is clean and very tasty. The flour obtained from the sève is dry and very fit for cakes," &c. (Com. Board Agr., vol. 1.)

8419. The propagation of fersus in pastures, where the plough cannot be used. The Highland Society having offered a premium for the best essay on this subject, two were produced and published. (Trans. H. S., vol. xx. p. 371.) In both, the writers, finding that fersus grew always in dry land, propose to cut it up for feed for the horses. A knowledge of the functions of the leaves of plants would have suggested the cutting off of these in their incipient state, as soon as they made their appearance above the soil, and consequently before they had time to return any nutriment to the root; which will not only kill fersus, but every plant whatever.

8560. The varieties of the horse described by Professor Love, are: 1. The race horse; 2. The hunter; 3. The Connemara, or Irish pony breed, of Spanish origin; 4. Classes of British horses: viz. Zetland ponies; Orkney ponies; Highland ponies; Welsh, Dartmoor, Exmoor, and Hampshire horses; hack horses, and Galloways of the borders; 5. The old English black horse; 6. The Cleveland bay; 7. The Suffolk punch; 8. The Clydesdale breed. (Love's Domestic Animals, vol. i.)

8561.—8565. A machine for fixing horses while being shod, of a simple and effective description, has recently been patented by Mr. James McTuleagh, millwright, in London. It is very great genius; which will be found described and figured in the Quart. Journ. Agr., vol. ii. p. 510.

8562.—8568. Rodway's concave horse-shoe is particularly applicable in the case of horses that have to pass over wool pavements; and it is also said to contribute much to the comfort of the horse in every other position. (Brit. Agr., vol. xi. N., S., vol. ii. P. 456.)

8563.—6564. The following plan of feeding horses has been practised by Dr. Sully of Wiveliscombe, in Somersetshire, for upwards of twenty years. In Dr. Sully's stables there are no racks for holding hay; for in his opinion a horse with a well-filled rack will consume and spoil upwards of thirty pounds of hay in twenty-four hours; whereas, if the hay were cut down, and mixed with a due proportion of cut straw, and bruised or coarsely ground oats or other grain, ten pounds are sufficient. In the loft, above the horses, Dr. Sully has prepared proportionable quantities of the food with which his horses are daily supplied; and a very simple method has been devised to convey it, when mixed, to the manger of each horse. A wooden pipe is made to pass from the loft into each of the mangers, and close by the mouth of the pipe, in the loft, is placed a tub, of size enough to contain what is sufficient food for a horse for twenty-four hours. To prevent the horse, in searching for grain, from getting to the bottom of the mixed food which is dropped into it, oak crossbars, twelve inches distant, are nailed over it; between these bars ample space remains for the horse to feed. As there can be no dependence on the measured quantities of food, from the loft, or other food given to the horse, the times in the respective weights of equal quantities, Dr. Sully recommends, and, indeed, regards it as necessary, that grain and hay, and the other foods, and also the cut hay and straw, should be carefully weighed. When all the ingredients are so prepared, the proportions for each horse are allotted. From the following table will be seen the different articles of food, and the quantities and weight of each, which the horses should receive:

With two ounces of salt for each class. By this table it will be seen that each horse receives 30 pounds of food in the twenty-four hours, a quantity that will in all cases be found to be amply sufficient. The addition of two ounces of salt is necessary to assist the digestion of the food. Of the four classes into which Dr. Sully divides his ingredients for feeding, those of the steamed or boiled potatoes are the most recommended. No food conduces more to the healthy working condition of horses than the steamed or boiled potatoes; and we may observe, with relation to this, as well as to other kinds of food, that, when the horse comes in weary and hungry, after a long day's work, it is necessary to fill his manger more copiously than when he is satisfied. As the ingredients prepared by Dr. Sully, the ingridients prepared by Mr. James McTuleagh, and the persons who have devised improved methods of feeding agree in the practices of bruising or coarsely grinding the grain and beans, of cutting down the hay and straw, of giving no hay in the rack, of allowing no manure or anything else to any weighing of the article separately before mixture, instead of adopting the fallacious guide of measurement. (Quart. Journ. Agr., vol. ii. p. 727.)

8544. Road horses, in some parts of Scotland, and more especially in the neighbourhood of Edinburgh and Ineburgh, are generally fed on equal proportion of straw and hay, cut by a machine in the lengths of from one eighth to one sixteenth of an inch. The cut straw and hay so prepared are intimately mixed together, and, when musty, sometimes sprinkled with a little salt and water. The drink given to the horse is water in which oats or barley have been boiled, and the grain so boiled is found to equal double its quantity in keeping the horse in condition; whereas, in some parts of Scotland, where the soil is clayey and of a nature to retent moisture, no drink is given to the horse, the horse being satisfied with the water of the stream. (Trans. H. S.)

8546.—8567. Feeding horses. As the result of an experiment tried with boiled grain, raw grain unbruised, and raw grain bruised or cut, it appears that by far the most profitable mode is to give the grain unbruised or cut. (Trans. H.)

8546. The oz. "The important family of which the common ox may be regarded as typical, divides itself into three groups,—the Bovinae, the Bubalinae, and the Taurinae. The bisons inhabit both the Old and New Worlds, and are distinguished by round, smooth horns, and a musky odour which exhales from the skin. The hoflares are characterized by angular horns, and a fainter odour of musk, and are natives of the warmer regions of Asia and Africa. The taurine group, comprehending the common ox and its different races, forms the most important division of bovinae." (Lowe's Domestic Animals, vol. i. p. 1.)

8547. The varieties of the Taurine group described by Professor Lowe are: 1. The wild or white forest breed; 2. The Highland breeds, the finest of which is the West Highland; 3. The Zetland. 4. The ponies of the Galloway, the finest of which is the Welch, or Border Galloway. 5. The Kerry. 6. The North Devon. 7. The Sussex. 8. The Glamorganshire. 9. The Herefordshire. 10. The Aberdeenshire. 11. The Vassilvans. 12. The Llanbadarn. 13. The Argyshire. 14. The Sulliford. 15. The Falkland. 16. The pollof Irish. 17. The Shetland; and 18. The long-horned. 19. The Tresswater short-horned, or Durham. (Lowe's Domestic Animals, vol. i. p. 1.)

8548. The points by which the different breeds of cattle may be judged, are given in the Quart. Journ. Agr., vol. v. p. 199; vol. vi. p. 265-453, and 546, by Mr. James Dickson, cattle dealer, Edinburgh, in a superior manner, and to anything of the kind which we have before seen in print. We can only spare room to extract a few features.

1. The short horns. The frame exhibits a straight line back from the horns to the top of the
tail, full buttocks, and a projecting brisket; in short, the form is rectangular and perfect in its kind. The colour is red, and the richest white, approaching to cream, or both colours are mixed. Limbs small and clean, like those of the race horse, uniting strength with firmness. Head small, lengthy, tapering, nearly set on a broad firm deep neck; mildly beaming eyes, thin large veiny ears, and semi-circular horns; in weight, short heavy horns, in texture, a symmetrical harmony, which has never been surpassed in beauty and sweetness by any other variety of the domesticated ox.

2. The Shetland breed are uniformly black, light red, or black and white. "They are naturally the smallest of the cattle, being generally from 16 hands to 20 stones; and when extra fat, from 25 stones to 30 stones. The beef is of the very finest quality throughout, being as small in the grain as mutton; the fat well intermixed, and the flavour most delicious. In fact, in point of quality, they are, without exception, the finest cattle that are bred in the kingdom. The cows are of the smallest, butchers, the bulls, but those of the Orkneys."

3. The Orkney and Caithness breeds. Orkney cattle are much larger than those of Shetland, and less symmetrically shaped. They are slow feeders, and incapable of early maturity. The Caithness cattle resemble those of the Orkneys.

4. The North Highland breed are bred in the counties of Sutherland and Ross. They are large, symmetrical, and feed well.

5. The Herefordshire breeds are middle sized, symmetrically black, and capable of being fattened at any age from four years to sixty stone.

6. The Angus breed. Middle size, symmetrically black, quiet, and rather slow feeding.

7. The Eife breeds have rather a ragged outline, and are in general symmetry inferior to those of the northern province, more marked in the expression of the eye dull. They have not an aptitude to fatten at an early age, but at four or five years they feed to great substance and heavy weight.

8. The West Highland or Kyle breed, is the oldest in Scotland. Form symmetrically, legs short, eyes full and sparkling, colour generally black; the newest Scotch breed in character and properties to the short horns.

9. The Ayrshire breed is celebrated as milkers, but the Tweed-side short horn cows are now being preferred, as on the whole the most profitable; they are larger, give more milk, and take up less room, and give less trouble in proportion to the quantity of milk they give.

10. The Galloway breed is readily known by being without horns. The head is rather large, and looks coarse; the legs are short and strong; colour mostly black. The beef, when well and long fed, is of first-rate quality.

11. English breeds. The Hereford is preferred, because they show, when fat, symmetry and points the nearest approach to the short horn; the others are bad milkers, and can give no more than two or three stones of the milk. They pay the feeder better than the breeder. The long horn fed to great weights, but they are rather coarse in the bone. The Sussex cattle are large, red, deficient in symmetry, and market fat. The East Riding and the Yorkshire breeds are inferior to the above. The West Riding breed, from the Demesne at Beverley, are a very fine breed, and are very well fed and milked. They are a hundred and twenty to one hundred and thirty pounds for making butter. The Welsh breed have thick horns, thick coarse plain hides, and narrow backs, and altogether are a very inferior breed. Graziers and feeders out of Wales never think of purchasing them when they can find Scotch West Highland or Kyle breed.

12. The Isle of Man breed is of a mixed character, combining various shapes and colours, so that, in short, there is properly no breed.

14. The Ayrshire and Jersey breeds are too delicate for the climate of Scotland. The Guernsey breed are not the Guernsey breed. They are ill made, give excellent milk, get fat on the rumps, but they are always thin on the ribs, and the beef is generally of a yellow tinge. (Quart. Jour. Agr., vol. vi. p. 568.)

15. The points or parity which cattle are judged have been laid down in a masterly manner also by Mr. Dickson (Q. J. Agr., vol. iv. p. 139.), and applied to the different Scotch breeds in the subsequent volume of the same journal. The first point is the purity of breed, which is ascertained by the colours of the skin being definite, and in particular by the horns and the nose. In this breed, the horns are black, the nose yellow, so that the form of carcass, which, taken longitudinally and horizontally, ought to be that of a solid parallelogram. A third point is a full, clear, and prominent eye. The next is the state of the skin, which ought to be mellow; a feeling which can only be understood by long practice. Sharp may be judged by merely the same and the expression of the eye dull. They have not an aptitude to fatten at an early age, but at four or five years they feed to great substance and heavy weight.

16. The Meath breed are not the Meath breed. They are ill made, give excellent milk, get fat on the rumps, but they are always thin on the ribs, and the beef is generally of a yellow tinge.
to be doubly nutritious to horses, yet, from a number of experiments made by recent farmers, with a view of the premium of thirty sovereigns offered by the Highland Society of Scotland, it has been given as an opinion that, in the case of the ruminating animals, no advantage whatever results from cooking their food. (See High Soc. Trans., vol. x. p. 235.)

The feeding of cattle in winter. An excellent paper on this subject will be found in the Quarterly Journal of Agriculture, vol. ii. p. 228—241. Some difference of opinion exists among agricultural writers as to whether young growing cattle ought to be fed, or pampered, as Dr. Coventry says, "as a baby," or supported on as much abundance of coarse as possible, while referred to inclines to the former opinion, on the principle of its being the farmer's interest to treat his cattle in such a way as shall enable him to bring them soonest to market. Coarse food, he says, ought not to be found on a well-cultivated farm. Straw and water, in an agricultural sense, are not food at all. Straw given to a generative period of being centralised, and can be given to cattle in the forwarding of their condition. A limited supply of turnips will keep cattle alive, and may prevent them from falling off in flesh, but it will never bring them to a state of fatness, though they were to eat it in the most moderate length of time, whereas a due allowance of hay will constitute abundance. Scanty food renders cattle uneasy; whereas food in abundance renders them contented and able to endure every inclemency of weather. A farmer ought neither to rear nor purchase meat that has been in the barn or hayloft; he should keep in a sufficient number, both on individual farms and in the country in general, of cattle of every age, to enable his market to be greater, and its quality better, than it now is. Hence, on the score of profit to the farmer, and case and comfort to the cattle themselves, abundant nourishment ought to be given to the feeding-beasts. The above is the opinion of Dr. Coventry; he does not, however, insist on the cattle, and tied to stakes, or in what are provincially called "hammels," which are small open courts, with an open shed for shelter on the north side. Twice calves, or ten yearlings, may be put into one of these. A hammel with a shed seventeen feet in width and fourteen feet in depth, with a court twenty-one feet by seventeen feet, will contain three large oxen, or four smaller-sized cattle. Every hammel must be supplied with pure water at the command of the cattle. Before the cattle are put into hammels or byres, the floors ought to be well littered, so as to form a sort of drain to carry off the urine to the dung-pit. The byre must be prepared before the cattle are driven in. Straw; and therefore the first thing that should be given to them in the morning is turnips, the troughs for holding them have been previously cleaned out. In the byre, the first thing to be done in the morning is to throw the dung from behind the cattle, with only a small portion of eating their turnips, the dung can be wheeled to the dunghill. Fresh straw, for fodder, may be given about the time that the turnips are eaten up, a small quantity being placed before each beast in the byre, and there eaten. Olive, or oat-straw is found to constitute the best fodder for cattle; potato oat-straw is, perhaps, better than that of the byre, as the farmer is able to get it a day before it is quite ripe. Hay is, no doubt, better than any kind of straw; and those who have abundance of that desirable fodder may give it ungrudgingly to cattle, in the certainty of being soon repaid its value. This subject is, however, given again another day; and should the latter be cleared out, and straw or chaff given. In the byre, after this allowance is eaten up, the mangers should be cleaned out before giving another foddering of straw. A troxel will be found a handy instrument for this purpose. At a certain time of the year, the last fodder given, is the last allowance of turnips, which should be ample, as the cattle will come backward and forward to them even in the dark, and in moonlight they will feed as well during the day. The calves should be served with turnips immediately after the feeding-beasts; and the year-oxen can also get a few at this time, to overcome any scrawls. Some allowance of straw, the mangers, the byres and the hammels, to induce the cattle to lie down after repast, to chew the cud, which they will invariably do. At eight o'clock at night, the byres should be looked at with a light, and the cattle supplied with the fodder necessary, and their beds made comfortable for the night, by drawing back any dung that may be on them, sprinkling some more litter, and shaking it well up with a fork. At the hams, if it is moonlight, some more turnips should be thrown, even at this time of night, into the mangers. During the day, the water-troughs should be all kept full of fresh water, and any filth that may have been blown into them by the wind should be removed. When the frost becomes so severe as to harden the turnips, they should no longer be brought from the field, but from the store formed of them in the beginning of winter, for the purpose of supplying the cattle with fresh turnips during the continuance of the season. The young cattle can be taken every day, for the winter will there be. When they are supplied with food at irregular times, they will either be always craving it, or become careless about it; and their uneasiness, arising from frequent disappointments, will prevent them from feeding so pleasantly and speedily as when their food is placed before them at exact periods. When the man thus regulates his different works by time, he will find less moments during the day to perform many necessary acts; which, though they may appear of little importance in themselves, nevertheless contribute greatly to the appearance of neatness and comfort in the farm-yard and its inmates. Thus, he may give some of the turnips, with the stalks or heads, to the edge of the old-cattle, to keep any turnips clean that may have been pulled over by the beasts; for, when cattle are first put up to feed, the freshness and tenderness of the leaves induce them to eat these first, and in the anxiety of each to obtain another mouthful, many turnips are necessarily torn up. Hence, it is necessary to rub together any mud about the causeways, and the places on which the turnips have been laid down from the field. He can frequently examine the skins of the cattle, and give immediate notice of any erup- tions with the fodder necessary, and their beds made comfortable for the night, by drawing back any rough of which causes ulcerated spots to break out, but which can easily enough be cured at first, by an application of a decoction of tobacco, with a little spirit of tar. He should rub those parts of the body which they cannot easily get at to lick, with an old currycomb, and scrape off any dung that may have accreted thereon. He should also take care not to let the cattle ram in the kennels, and keep a sharp lookout. Their attention is more necessary at the beginning of the season than afterwards, as the freshness of the stems, and the juiciness of the roots of the turnips, and the greediness which all cattle evince for them at first, may cause them to swallow them in the most unwholesome manner. They should be turned into the hard ground in the early part of the spring, when these may be easily destroyed, by applying to the affected parts a solution of mercurial ointment; but, if neglected, they will cause much uneasiness to the cattle, making them restless and impatient, and an unwholesome skin is likely to ensnare them on every part of their body, as they are very fond of being handled when they are rising in condition. This is also serviceable to familiarise them with man; as cattle, when they have been accustomed to be handled, will stand better, and show themselves more satisfactorily to the buyer. There is something so winning in these animals, in powerful social beauties, caused, no doubt, by nature, which the hands in particular, when they have to be driven a distance upon the road; and the butchers in the neighbourhood will also prefer them, as they will walk peaceably to the shambles, without the risk of being raised to a frenzy. All these constitute the minutiae of the business of feeding cattle on turnips in winter; and, trifling as they
may appear, attention to them will be amply repaid, in the shape of prime beef and doctile cattle. The whole may be easily accomplished by any man who regulates his movements by the watch; and the man having the charge of cattle in winter, who will do this whether he is seen by his master or not, is an estimable servant.

8464. The quantity of turnips which feeding cattle will consume, as stated by most writers, is about one ton every week, for an ox of from sixty to seventy stones, or about one acre of a fair crop of turnips in three mounth. Thirty-three loads of turnips, each weighing from sixteen cwt. to eighteen cwt., are a good crop on light sharp lands.

8465. Time of putting up to feed. If the second growth of grass has continued fresh till the latter part of autumn, cattle may be soon enough put up to feed by the 1st of November, but if it should be frozen or frosted before, it will be necessary to wait till the middle of December, which it will in most seasons do, the middle of October is late enough for putting them up to feed. White globe turnips are an excellent juicy food for cattle till the commencement of the new year, after which should follow the yellow or green tops, for two months longer, and then the Swedish turnips will finish the season. If the Swedish turnips have been stored up late the second growth or the new season goods has made its appearance in spring, they may be taken out quite fresh till the beginning of June. Since the cultivation of the potato has increased so rapidly, many people feed their cattle on it in spring either wholly or mixed with turnips. When the potatoation ought to have been discontinued, it is expedient to allow of feeding, for fear of internal swelling. When observed at first, the swelling may be allayed by pouring down the throat a bottleful or less of common wool oil, which will check the fermentation, and operate as a purgative. Should any of the young cattle or the feeding beasts, or a piece of turnip, for those fed in hammers never or very seldom do so, the best expediency is to use the probang at once, rather than to permit the throat of the poor animal to be squeezed, and consequently inflamed, in attempting to push the piece of turnip up and down. The probang may be used with great success, by coating the handle thereof to be forcibly held by superior strength, which, when once is put in, and while one is pushing the instrument gently down, another is directing the end of it down the gulet on the outside of the neck. When the piece of turnip is pushed down into the stomach, the instrument can easily be left in it, and if, during the operation, the animal forcibly twist its twine, the instrument should instantly be let go. Feeding cattle will eat very little straw; but they ought to have abundance of litter at all times.

8466. Comparative merits of feeding cattle in hammers and byres. Our decided predilection is in favour of feeding cattle in hammers. In them the cattle are at perfect liberty to roam about, if disposed for exercise: they are exposed to all the sunshine there may be in a winter day; and the very rain which falls on their backs titillates the skin, and causes them to lick and clean themselves: they are comfortably warm in their sheepskin and thigh-length draw in the coldest night, and cattle will not suffer from exposure in them when they have a comfortable shelter to which they can repair at will; they can come and go to their food whenever they please there, night and day, and, their meat being constantly in the open air, it will be always fresh and sweet; and the cattle are to be expected to live longer in the fresh air and the coldness of the air. These are all advantages which no byre can couier. Nor are the hammers so expensive in their original erection as many represent them to be. We have seen a range of them consisting of five divisions, capable of feeding twenty large oxen, erected for 2l.; but these had no regular roof. The roofing of all buildings is the most expensive part of them. The roof of those to which we refer, consisted of trees laid across as beams, about a foot asunder, the space between them being filled up with the branches of the spruce fir and Scotch pine. Such a place was a choice one for stacking pens or branches; it was often appropriated to that use; or it was used for storing provisions, or roped down, which was used as bedding for the cattle in the first part of the succeeding season, when fresh straw was put in its stead. In the hammers which faced the south, the cattle were well fed and comfortably lodged; and no byre could have afforded so much accommodation at the same expense.” (Quoted Scare. Agr. vol. ii. p. 241.)

8467. Mill is preserved from becoming acid by the addition of any alkali; because, when milk ferments, it develops an acid, which the alkalies neutralize. Hence alkalies prevent the curdling of milk. Alkali acids being not unpalatable, and in large quantities give the milk a disagreeable flavour. (L’Agriculture-Manufacuyeur, Mai. 1831.)

8065. A curd-breaker for skim-milk cheeses (figs. 1184 and 1182.) has been invented by Mr. Robert Barrie, of Gilfarch Place, Edinburgh. It consists of a hopper of wood (fig. 1181, a), seventeen inches and a half by fourteen inches on the top, and ten inches in depth; and a cylinder of hard wood six inches and three quarters (b) in length, and three inches and a half in diameter. The cylinder is studded with square pegs made of iron, being loosely put together; can be easily each, a quarter of an inch in the side, cut square at the ends, and projecting three eights of an inch. There are eight of these, in the length, and fifteen in the circumference, of the cylinder, 120 stove in all. It revolves on a round iron axle twelve inches long, and is moved by the crank handle (d in fig. 1182); c are two wedge-shaped pieces of hard wood, made to fill up, in some degree, the space between the side of the hopper and the cylinder. These pieces rest on a slip of wood placed to the lower rim of the hopper, to keep them in their place. The face of these is studded with nine teeth of hard wood, similar to those on the cylinder, at equal distances. The stand (e) (fig. 1182) can be made of any length, to suit the breadth of the tub into which the curd is broken. The implement is used in this manner: Place over it a tub, heap the hopper (a), with curd, and, on the top of which (c) is placed, the excision, the curd will fall, broken, or small, into the tub. While one hand is moving the machine, the other can press the cylinder gently down into the hopper. As cleanliness is a matter of the greatest importance in cheese-making, the internal parts of this machine, being loosely put together, can be easily taken to pieces to clean. The cylinder axle rests on two hard wooden blocks (f, fig. 1182), one on each side, which slip out of their groove. They are held in their working position by the thumb-catch
(g), sunk flush with the bottom of the stand (c), one over each block. The wedge-shaped piece (c, \textit{fig. 1181}) came out. To prevent the curd working out of the sides of the axle, the cylinder is set a little at both ends into the sides of the hopper. The dotted lines in \textit{fig. 1182}, will give an idea how the internal part of the machine is constructed. Only one tooth is represented on the cylinder by the dotted lines, to show the position of the whole. (\textit{Quart. Jour. Agr.}, vol. iv. p. 385.)

\textit{Fig. 1181.} Baird's cheese press (\textit{fig. 1183}) is one of the most convenient in use. "The form containing the curd is put on the bottom plate, A, and the top plate, \textit{n}, is made to descend and press on it. There are two ways of doing this: one quick and easy, and the resistance becomes great; and the other slower, but more powerful, and uses two three turns of which will make the rack descend through a space corresponding to eight of its teeth. In this way the plate \textit{b} may be lowered to touch the cheese, and to commence the pressure; but when the resistance becomes considerable, the second method of acting on the rack must be resorted to.

On the axis \textit{r}, besides the pinion before-mentioned, there is a fixed ratchet wheel, \textit{F}; the lever \textit{i}, forked at the end, which embraces \textit{p}, is also placed on this axis, but turns freely round it. In the forked part of \textit{p} there is a pail or click, \textit{G} (better seen at \textit{a}+), which, turning on the pin \textit{k}, may be made to engage in the notches of the ratchet-wheel \textit{r}. By means of this arrangement, when \textit{i} is raised up, and the pinion \textit{p} engaged in the axis \textit{r}, and its pinion, will be turned round with great power on depressing the end \textit{r} of the lever; and by alternately raising and depressing \textit{i}, any degree of pressure required may be given to the cheese; after which, if it be wished to continue the pressure, and to follow the gradual shrinking of the cheese, the lever \textit{i} is to be raised above the horizontal position, and the weight \textit{W} hung on, which will cause it to descend, as the cheese yields. By inserting the pin \textit{p}, this effect may be discontinued, and the farther descent of \textit{n} prevented." (\textit{Highland Soc. Trans.}, vol. x. p. 82.)

\textit{Fig. 1182.} \textit{The pneumatic cheese press} (\textit{figs. 1184. and 1185.}) is the invention of John Robson, Esq., Sec. R.S.E. When full size, this press may consist of a stand about three feet high, on the top of which may be fixed a wooden or zinc vessel, of any required capacity (say eighteen inches diameter, and eighteen inches deep), to contain the prepared curd. This vessel should have a loose bottom of ribbed work, covered with wire-cloth, from under which a small tube, nearly twelve inches long, should communicate with a close vessel, capable of containing all the whey which may be drawn from the curd in the upper vessel. At one side of the stand there may be a small pump-barrel of about seven inches deep, from the bottom of which a suction pipe should terminate at its upper end in a valve opening upward, and a piston, with a similar valve, should be placed in the pump-barrel, and be worked by a jointed lever, as shown in the model. The process is to be conducted as follows:—The curd being prepared, and salted in the usual way, a cloth is to be put over and into the upper vessel, and the curd put lightly into it, except round the edges, where it should be packed quite close to the sides of the vessel, so that no air may pass that way; the handle of the pump is then to be briskly worked for a few minutes, on which the pressure of the external air will force the whey to run down the tube into the whey-vessel; when it ceases to run, a few strokes of the pump may be repeated. The cloth and its contents are then to be raised bodily out of the curd-vessel, and to be put into a mould of close wirework, with a weight placed over it until it become firm enough to be handled. The mould should stand on a sparrow shelf (a shelf made of laths like a bacon rack) to allow the air free access to it on all sides of the cheeses. In \textit{fig. 1184}, \textit{a} is a vessel containing the curd; \textit{b}, a vessel for containing the whey; \textit{c}, a tube communicating from \textit{a} to \textit{b}; \textit{d}, an air pump for exhausting the air in \textit{b}; \textit{e}, a tube communicating from \textit{d} to \textit{b}; \textit{f}, a tub for letting off the whey from \textit{a}. \textit{Fig. 1185.} is a false bottom for the vessel \textit{a}; \textit{g}, wood frame; \textit{h}, wire-cloth. (\textit{Highland Soc. Trans.}, vol. x. p. 200.)
mellilot, which smells exactly like a pigsty. (G. C. 1842, p. 308.)

876. —7184. Management of the fleece in Australia. In order to assimilate the Australian wool as much as possible with the German, in preparing it for market, the fleeces should not be broken, but merely divided of the breech and stained locks, and each part of each lock contain fleeces of the same character as to colour, length of staple, fineness of hair, and general quality.

877. If the washing has been performed at the same time and place, and with an equal degree of care, the colour is likely to be uniform, and it will then only be necessary to attend to the separation of the fleeces as to length, fineness, and general quality; but if a large number of different sorts, and fed on different soils, care should be taken that the fleeces be separated, first, as to colour, and then, again, as to length, fineness, &c.

878. Packing. The fleeces, being assorted as already suggested, should be spread one upon another, the neck of the second fleece being laid upon the talk of the first, and so on alternately to the extent of eight to ten fleeces, according to their size and weight. When so spread, the two sides should be folded towards the middle, then rolled together, beginning at the end in the centre; and the roll or bundle, so formed, should be held together by a slight packthread.

879. The bagging should be of a close, firm, and tough nature. The material hitherto most generally used has been sail canvas, which very ill resists bad weather on a long voyage, and, when received here, even in favourable condition, is so dry and crisp, that it will tear like paper. A thicker, more flexible, and tough material would be preferable. The size and form of the package may be in length about nine feet, and in width four feet, sewed up on the two long sides, and at one end; the other end being suspended with the open direction to receive the bundles. In this position, it is to be put in at one time, one of the flat sides of the roll or bundle being put downwards, and so on in succession; and the whole being well trodden down, until sufficiently filled for the mouth to be closed. This is the German mode of packing, but it is probable, that the simple and obvious contrivances that have been hitherto sent from the two colonies may not be more convenient for so long a voyage.

880. The operation of screwing should be discontinued where it has been practised as the pressure of the screw, and the remaining compressed during the voyage, occasions the wool to be caked and matted together in a manner that is highly prejudicial to its appearance on arrival. The best mode of winding up each fleece separately, and twisting a portion into a band, is productive, in a minor degree, of the same prejudicial effect, and it is to avoid this that the making German bundles of eight or ten fleeces is suggested. (G. Low's Norfolk Sheep, p. 3, 834.)

881. —7319. Feeding sheep. It is well known, from the discoveries of the first chemists, that turnips are deficient in nitrogen, and that all animals require a portion of it for their healthy nourishment. Clover and meal contain, besides other nourishing substances, a sufficiency of nitrogen for the supply of animal flesh, and their addition greatly increases the feeding quality of turnips. Much of the juice of the turnips remains undigestible, and is voided without any change, when they are the only food of the sheep, which more nitrogenous food would enable the stomach to decompose; at least such is the prevailing theory; and it is very plausible. Experiments and accurate observations alone can substantiate it, or refute its truth. (G. C. 1843, p. 132.)

882. Feeding sheep in a shed, though they consume nearly one fifth less food, made above one third greater progress. (J. W. Calvert, Esq., in Journal A. E., vol. i. p. 169.) Subsequent experiments exhibit still greater advantages, particularly during the winter months. By giving the sheep cake, and a

---

8471. Atwood's newly invented churn (fig. 1185), "being made entirely of block tin, the necessary degree of temperature can be given to the cream, by placing it in a pan of cold or hot water, which ensures the butter coming in ten or twelve minutes of the season of the year. The simplicity of its construction, and the advantage which it may be cleaned, are no insuperable advantages over those now in common use. The great advantages will be found in the winter; but in the heat of summer, the placing the churn in cold water will be the means of hardening the butter." (Johnson's Agr. Imp. for 1843. p. 14.)

8472. —7010. A stoneware churn, of which fig. 1187, is a perspective view, has lately been invented, or brought into notice, by Mr. Daniel Chambers, of Carey Street, London. In form, and in the manner of using it, the stoneware merely respect the same as the patent box-churn, figured in page 1040; but the advantage of the present invention is, that, being made of earthenware, it is much easier kept clean and sweet, than when made of wood. The rate of that which we have given a figure is the smallest that is made, and it will churn so small a quantity as half a pound of butter at a time. As this churn, from being made of earthenware, is rather too heavy for being lifted up and emptied, there is a small hole on one side near the bottom (indicated in the figure), to let off the butter-milk; which hole is easily stopped with a common cork. The lid has a rebate, as shown at a, as a protection from the heat of the fire, and to prevent the milk from splashing over during the operation of churning. We have much pleasure in noticing this invention, because it will not only greatly contribute to cleanliness, and to the neatness of the butter produced, but also to lessening the labour of the dairy maids in scalding and scouring. (Gard. Mag. 1859, P. 14.)

8473. —7086. New Stilton cheeses may be made to acquire the flavour and appearance of old ones, by inoculating them with portions of the old cheese containing blue mould. The little scoop which is used in taking samples of cheese, affords a ready means of performing the operation, by interchanging ten or a dozen of the rolls which it extracts, and placing them so as to disseminate the germ of the blue mould all over the cheese. A new Stilton cheese treated in this way, and well covered up from the air for a few weeks, becomes thoroughly impregnated with the mould, and generally with a flavour hardly to be distinguished from the old one. (Highland Soc. Trans., vol. xi. p. 233.)

8474. —7093. Schatzsteiger cheese is flavoured with the bruised seed of Melichis schatzgiuss, or blue
little crushed barley, they may gain from 35 lbs. to 40 lbs. a head in the course of ten weeks, at that season. Much of the success depends on having a boarded floor, which prevents the sheep from taking the foot rot. (Ibid. p. 410.)

8458. A rain-proof feeding trough for sheep has been invented by a farmer of Fifeshire, Mr. Bell, near Cupar, and is described and figured by Mr. Huest. It is an adaptation of the common sheep's feeding box to the sheep trough with the addition of a simple application of the bird cage watering glass. (See Quarti. Jour. Agr., vol. xi. p. 115.)

8487. The varieties of the hog described by Professor Lowe, are:—1. The wild hog; 2. Siamese or Chinese breed; 3. The old English breed, and 4. The Berkshire breed. (Low's Domestic Animals, vol. i.)

8485.—7315. Preparation of food for swine. Mr. Bolton, who has fattened swine to an enormous weight, has the following observations on the subject in the British Farmer's Magazine, vol. vii. We consider them worthy of quotation, with a view of impressing on the mind of the reader the importance of feeding fish to this class of animals:— "I always feed my pigs on sour food, which I have invariably found to feed them faster, and to make the flesh firmer and whiter, than food given in any other state. The following is my method of preparing it:—As soon as the potatoes are steamed, I have them, while quite hot, beaten to a pulp, and mixed with bran, in the proportion of twenty-eight pounds of bran to a sack (240 pounds) of potatoes, and this mixture is put into a vat for ten or twelve days, till quite sour; this food makes the pigs fat enough for porkers or small bacon. When I require them more than commonly fat, I begin with fifty pounds of barley flour, instead of the bran, to each sack of potatoes, gradually increasing the quantity of flour till it amounts to half the weight of the potatoes: when the quantity of flour is greater than the moisture of the potatoes will absorb, I add a sufficient quantity of water to make it into a thick paste; I never give it until it has fermented."

8486.—7315. Pigs in Hampshire are frequently washed and rubbed with a hard brush, which is found greatly to improve their condition, and is one of the principal causes of the bacon of that country fetching 2d. more per pound than that of any other. (G. C. 1842, p. 351.)

8487. A description of Mallet's improved apparatus for cooking fodder for cattle by steam. The simplest form of apparatus for this purpose, usually met with, consists merely of a common open boiler, over which is a tub with its bottom perforated, is placed, and the discharge rendered steam-tight by what is called a water-valve or water-lute joint; that is to say, by the lower edge of the tub projecting below its bottom, into an annular space round the upper edge of the boiler, filled with water. The tub is filled with the vegetable matter to be cooked; and the steam rising through the perforation of its bottom, from the water beneath (a fire having been lighted under the boiler), prepares it. This apparatus, excellent as it appears from its simplicity, has many disadvantages. The tub requires to be lifted on and off, by means of a Crane, if of large size; a separate boiler is required for each tub; there is no mode of regulating the supply of steam, but by damping the fire, or urging it; and the boiler, to be supplied with the water spent in steam, needs the tub to be previously lifted off. Added to all, the boiler must be circular, and, therefore, of the worst possible form for economy of fuel. The next form is that in which several steaming vessels are supplied from one boiler, which may be of any form. Each of these vessels consists of a tub, as before, with a perforated bottom, and close but moveable cover, which is placed on another shallow tub, with a close bottom, into which the steam from the boiler is conducted by a pipe from the boiler; the junction between the two tubs being made good, either by three or four thicknesses of felt, or by a gasket; a cock regulates the admission of steam to each lower tub, and a crane is provided, which commands the whole range, and lifts them on or off. The arrangement answers tolerably well, but has some inconveniences. But a comparatively small surface of the potatoes or other fodder is exposed to coction. The crane for lifting off the tubs, when each is capable of containing from four to six barrels of potatoes, requires to be a strong and rather costly piece of work; and the consumption of time and labour in lifting on and off, filling and emptying these tubs while hot, is very great, whereby a considerable loss in fuel accrues. All these considerations may be of small importance where the quantity of fodder to be fed with cooked food, and the apparatus is therefore nearly at constant work, every consideration of facility and economy becomes in the highest degree important. Accordingly, the following train of apparatus is designed for a gentleman, who is not only an extensive reaper of cattle, but one of the most distinguished agricultural improvers in Ireland. * It is conceived that it embodies most, if not all, that can be wished for the purpose. Fig. 1188. is a longitudinal section of the boiler, which is cylindrical, and

* Robert La Zouché, Esq., of Harriston.
boiler; at the extremity of which it goes off, right and left, through two lateral flues, which join at k, and go into the stack or chimney; e is the feed head, supplied either from any sufficiently elevated source, or by a pump; it is adjusted to supply the boiler at a pressure of 14 lb. to the square inch; a is the safety valve, loaded to the same pressure; the steam from it blows into the flue; f is the man-lid; m, a whistle, for the purpose of giving notice when there is a deficiency of water in the boiler, should such ever take place; below it comes the two links formed in projections from the adjacent hoop, and made steam-tight by a piece of bees' wax and tallow; it is capable of being very readily put on or taken off. In the lower segment of the cylinder, an arched wooden false bottom, d, is placed, stiffened by slight cross ribs of cast iron, and perforated full of holes five eighths of an inch in diameter; above, and supported by this, the matter to be cooked are placed until they quite fill the cylinder. The whole thing is hung upon two gudgeons or journals, c, c, passing through the centre of gravity of the cylinder, when loaded; so that, by the arrangement about to be described, either end of it may be elevated or depressed. One of these journals is hollow, and immediately connected with the steam-pipe from the boiler by a stuffing-box, f; so that the steam enters the bottom of the cylinder through this journal and the curved pipe g, the former having still free play in motion. Both journals move in brasses, resting on strong diagonal framing, h, h, bolted down to a mass of masonry. t, t, are two wrought-iron links, connected by joints with the hoops of the cylinder at top, and with the extremities of the equibrachial lever k; the centre of which consists of a Y shaft, l, supported by two or three slight frames, m, m, and having the long lever n keyed on it at one end. These frames are bolted to proper timbers in the floor of the loft above. Now it is obvious that, by means of the vertical lever n, either end of the cylinder may be elevated or depressed, and that the natural tendency of the whole system, when at rest, will be to remain horizontal. From the bottom or side of the cylinder at o proceeds a small tube, to take away the condensed steam; so made, that it shall permit the water to pass, and yet be steam-tight; and also that it shall remain vertical, whatever be the position of the cylinder. This is shown enlarged in fig. 1195. The upper end of the tube works in a steam-tight joint, a, like the pin of a common cock; but made so that there is a free passage through in all positions of the tube; the screw tail of this joint is secured into the bottom of the cylinder by a brass nut and felt washer; the joint being placed back with its axis at right angles to the axis of the cylinder. The lower end of the tube b (shown only in part) consists of an inverted siphon, the returning limb of which is of such a height that the column of water retained in it is equal in pressure to the density of the steam in the cylinder. The greatest part of the steam emerges freely in a square aperture, below the level of the floors in figs. 1189 and 1190, where it is connected with a small sewer to take away the water. It is evident that, when the cylinder is moved, the tube will rise and fall vertically in the hole or upright trunk in the floor. Now for the mode of working this steaming vessel. The steam being up in the boiler, and the lid e remov'd, the end c of the cylinder is steaming vessel. The steam being up in the boiler, and the lid e remov'd, the end c of the cylinder is raised, and the large roots requiring to be steamed; from whence they drop direct through the hopper and into the cylinder, where they are cut, or shon, by a machine, and in the cylinder, where they are cut, or shon, by a machine, and are then brought under the end e; the lid is removed, and the end e is now depressed sufficiently to cause the vegetable matter to fall out; the steam being previously shut off: the operation is then complete. The false bottom is now to be withdrawn, and it, together with the inside of the vessel, emptied of its contents; the former is only necessary when potatoes are cooked in it. The objects proposed in this arrangement

482
are, perfect ease in filling and emptying, without the necessity of handling either the heated vessel, or food; nearly a maximum capacity with a minimum cooling surface to the vessel; perfect staunchness, durability, and readiness of examination and cleansing of the interior. If there be no other elevated supply of water to the steam kitchen, a pump should be fixed in it, both to supply the boiler and to wash the vessels; potatoes, especially, leave a kind of slime upon the inside of steam tubes, which soon putrefies. It is said the cattle are sometimes choked by small potatoes, which are not sufficiently steamed; this might be prevented by the addition of a pair of rollers, into the hopper of which the cylinder might discharge its contents; and they would bruise all to a given size, and deliver into the truck before mentioned.

Fig. 1192 is a side elevation of the cylindrical vessel for steaming hay, chaff, bran, oats, clover, &c. It is of a much larger size than the cylinder for steaming more solid matters; and, therefore, is not made of wooden staves, but of iron plate riveted together like a steam boiler. Fig. 1194 is a cross section of the same; the letters of reference apply to both figures alike. The cylinder is supported on four vertical frames of cast iron, a a, properly connected by diagonal stays; one end of it is riveted in, and through it the steam-pipe b enters. The other end is moveable, and closed by a circular lid or cover, also of boiler plate, secured by six cotter bolts, as shown in elevation, fig. 1193; it is strengthened round its edge by a ring of two inches and a half angle iron riveted on, and is externally slightly convex; c is the convex false bottom, formed of sheet iron one eighth of an inch thick, punched full of round holes three tenths of an inch diameter, and stiffened by ribs of T iron, riveted to its lower side; d d are two siphon tubes for emission of condensed water, as before described: e is a man lid for the purpose of filling in chaff, &c., or other such matters. The large end lid has got a counterbalance weight attached to the chain f. The whole of this cylinder, and all the steam-pipes, are lapped over with slight haybands, which are lapped over with thick felt or dreednought; and this, lastly, is sewed tightly over with strong sail canvass painted. This mode of uniting, as a coating, several bad conductors having different conducting powers, is found to resist the passage of heat much more effectually than an equal thickness of even the worst conductor of the three. This fact, which, I believe, has not been hitherto noticed, will at once suggest to the scientific reader some curious analogies to the passage of sound through media.
of different density; and which, indeed, caused the arrangement which has been described to be adopted. It will thus be seen that this second cylinder is very similar in its general construction to that first described, except that it is not moveable; which, from its magnitude, would be inconvenient, and it is unnecessary for either hay or chaff, &c. Now of the mode of working it. In the loft above, immediately over the man-lid, is placed a chaff-cutter, and also a bean and oat bruiser, which both discharge by separate hoppers into the cylinder. The end lid having been put on and centered up steam-tight, the vessel is thus filled with the desired material, which is spread uniformly with a fork through the man-lid. Steam is then turned on; and, when the operation is complete, the end lid is loosed and thrown up by the aid of the counterbalance above the cylinder end, and the contents drawn out by forks, or by a large but light and slender instrument like the worm of the ramrod of a gun. Before being used the first time, the inside of this vessel is given a coat of drying oil and copal varnish mixed, which prevents subsequent oxidation. The general intent of the whole of the apparatus is to save labour and fuel, which it does effectually; and that portion of it for cooking potatoes is now about being erected in the new gaol of Mayo, the largest in Ireland. In some few cases, where the extent of the apparatus would be very great, and labour dear, it might be advisable to connect a small steam-engine with it, working from the same boiler, to pump water, slice turnips and mangold wurzel, cut chaff, and bruise oats and beans, &c. Where a high pressure steam-engine pre-exists on a farmery for other purposes, the waste steam from it may be made fully available for steam-cooking apparatus, which thus would cost nothing; it requires, however, a particular adaptation, in order that the power of the engine may not be reduced, by driving the steam through any considerable resistance. Occasionally, but rarely, fluids may require to be boiled by steam, as stirabout for pigs, or wash for calves; for these, another form and construction of vessel altogether is necessary. (R. Mallett.)

8489-7431. Warmth is strongly recommended for promoting the health of poultry. Cold, it is found, either produces inflammation of the lungs, or pulmonary consumption. Heat constantly prevents this, and alleviates the disease when it has taken place. (Annales des Sciences Naturelles, as quoted in Quart. Jour. of Agr., vol. ii, p. 56.) Warmth, also, makes fowls lay. Every housewife knows that eggs are most abundant in warm weather; and all country housewives know that the only way to make hens lay in cold weather, when eggs are dear, is to
ized, and cheaper (see Gard. Mag., vol. v. p. 586.), sold by Messrs. Bailey, 272. High Holborn, and by Weir in Oxford Street, but it is by no means so durable.

1356. The mole may be operated on without the use of traps by digging up the mole hills in the course of the month of March, which is the breeding season. In order to give an idea where the mole's nest is to be found, reference may be had to figs. 1197. and 1198; the first of which is an underground plan, or horizontal section of a mole-hill, and the second a vertical section. In both these figures, a is the mole's nest; b, vertical tubes or runs, by which the mole ascends with the soil which it has excavated from the place forming the nest, in order to raise a hill over it to protect it from the rain; c c show the surface of the ground; d, a tunnel above the surface of the ground, in the soil of the artificial hill; e e, the common run of the mole extended to an unascertained length on every side; f, line indicating the base of the hillock. After removing the hill, and destroying the young moles, by waiting a little without making the least noise, the parent will make her appearance and may be also destroyed. (L'Igromone, vol. i. p. 220.)

491.—762. A mode of catching rats by baiting the traps with ground pale malt scented with the oil of caraway seeds, and which is said to be very effective, will be found described, at great length, in the Quart. Journ. of Agr., vol. ii. p. 319.—391.

492.—764. Wire worm. The refuse lime of gas works, probably an impure sulphuret of lime, or lime combined with sulphured hydrogen, a gas, the most deleterious of all others to animal life, has been found by Earl Talbot to check the ravages of the wire worm. (Proceedings of the Royal Agr. Soc. in June 1841.)
"We must go deeper for the causes of demoralisation than the mere assembling together of men and women in the fields. It is said by nearly all the witnesses that the women who work in the fields make neither good housewives nor good domestic servants. Now, to be neither a good housewife, nor a good household servant, is a grievous charge against out-field labour, were out-field labour chargeable with a result so much to be regretted. But the cause of the Dorset and Wilts, and Somerset and Devon women who have worked in the fields being such thriftless housewives, as they are mentioned to be in the Reports mentioned, is quite a different cause from that assigned. It is just as different as possibly can be, for it is that the unstable nature of all agricultural engagements in the south of England begots a precariousness of employment, with small and uncertain wages; which, by making good furniture and clothes, and family stores of provisions, unattainable, renders good housekeeping impossible."
The remedy which the admirable writer quoted suggests is, "Not the curtailment of the employment of women in the field, but an extension of it; a thorough revision of all the engagements between landlord and tenant; the complete emancipation of the tenantry from political subjection; the abolition of the variable rates of wages, dependent on a man's being married or unmarried; the establishment of agricultural schools for farmers; of national schools for all children, with no religious intermeddling whatever, save through the influence that may be exercised in the pulpit and in visitation to the houses of parents; an enactment compelling cottages to be equally good with those lately built by the Duke of Wellington for his labourers at Strathfieldsaye, with gardens not less in size, to wit, each a quarter of an acre; or as good as those cottages built for their workpeople by the Messrs. Ashworth and some other Lancashire manufacturers, as described in the Sanitary Report of the Poor Law Commissioners, published in 1842, and Suppl. Encyc. Cott. Arch. p. 1154. To discourage the giving of beer to labourers as a part of their wages. To encourage the paying of workpeople by so much a day, or week, or months, or year, and not by piece-work. To give tenant farmers full power to break up all old grass lands, and crop each his own farm, as he sees most fit; that is, if he proves himself to be trustworthy in regard of knowledge and capital. To give him security of tenure, that he may obtain capital. To take from him, at once and for ever, all delusion about protection from commercial competition, and let increased commerce give him an increased demand for his produce. To have all rents regulated by the prices of produce. To depart from the ruinous custom of an incoming tenant paying for all the work which the outgoing tenant has done in improvements, real or supposed. To let each tenant, on the contrary, come in free, and commence with his capital to improve his farm himself, giving him at least twenty years to reap the benefits, so that when he goes out he may carry the profits of his improvements with him, and not take their supposed value out of the pocket of his successor. To give better diet to the really helpless of the poor in the workhouses, and sufficient out-door relief to the aged who may desire to remain in the home of their affections. To send all able-bodied labourers who are willing to work and cannot find employment, to the cultivation of the crown lands, or other estates that may be procured and used for the purpose of agricultural schools; but never to send them to break stomes or grind bones in a workhouse, as a punishment. To put an end to all poaching and poachers, by putting an end to all game and game-laws, and giving gamekeepers a more useful employment.

These are a few of the remedies for the present condition of the farm labourers. They are hastily
thrown together. Some of them are, of necessity, remote; others I believe to be near at hand; all of them, I believe, must be adopted and carried out before the deplorable state of agricultural England alters from what it is. (One who has whistled at the Plough in Morn. Chron., June 24th, 1843.)

1199. The application of steam to machinery for raising the water from fen and low lands. We have mentioned (§ 7796.), that steam had been employed for this purpose in Cambridgeshire; and we have since learned from the account of a trial in the newspapers (see Times for July, 1834), that a gas engine has also been so employed in the Cambridge fens. We are now enabled, through the kindness of Mr. C. H. Capper, engine-maker, Union Foundery, Birmingham, to figure and describe a steam-engine and lifting machine of a very superior description, which that gentleman has erected on the estate of Drake, Esq., at Stainfield in Lincolnshire. "The great advantage," Mr. Capper observes, "of bringing fen and low lands (formerly rendered useless by floods) into cultivation, by a small outlay of capital, must be my apology for troubling you with so minute a description of the draining machine I have erected for that purpose; and, as the same may be of use to a few, I shall feel obliged if you will give it a place in your work; and at the same time add, that by the great improvements which the use of locomotive carriages has made in high-pressure engines, I am enabled to say that as effective an engine as the one described might now be completed for a much less amount; or, if the landowners whose lands are subject to floods were to subscribe, a movable draining-machine might be made, at a very small expense."

Fig. 1199. shows the elevation of a six-horse portable condensing steam-engine, working a second shaft, marked $c$, in figs. 1200, 1201, and 1202. On this shaft, the large water-wheel $d$ is fixed. This wheel revolves in a brick or stone casing, similar to that formed for the wheel of a common water-mill, but so accurately fitted as not to allow of any water passing by either of the sides of the paddles, or by the front; because this wheel acts by its paddles lifting the water from the bottom of the wheel-race up against the breastwork, and then throwing it over the sluice $e$. This sluice is formed of movable boards, to admit of regulating the lift of water at pleasure, from 3 feet to 8 feet in height. The water, being raised and thrown over the sluice $e$, falls into the pond or receiver $f$, whence it is carried off at as high a level as it will run; in this case, at about 8 feet higher than the surface of the lands to be drained, and about 6 feet higher than the bottom of the drain. At the lower end of the trough there is a sluice $g$, for regulating the quantity of water introduced into the lifting wheel; because, if this were too great, the power of the steam-engine might be insufficient to turn the wheel, or the machinery might be injured. The wheel, as it will be seen, consists of eight iron paddles, fixed to an octagon iron casing; each paddle acts by lifting up a portion of water from the boom of the wheel-race, and raising it to the top of the
When the whole of the water, or nearly so, is lifted up, of course the boards composing the sluice c must be attended to, lest the water force its way back again upon the wheel.

*Fig. 1200.* is a ground plan of the boiler, engine, and water-wheel; in which a is the boiler; b, the engine; c, the water-wheel shaft; d, the paddles of the water-wheel; e, the upper sluice, over which the water is thrown; f, the pond or reservoir which receives the water; and g, the lower sluice, placed across the drain which conveys the water to the wheel-race.

*Fig. 1201.* is a section through the steam-engine and the water-wheel; in which a is the boiler; b, the engine; c, the shaft or axle of the water-wheel; d, the paddles; o, the tube for supplying water to the boiler; p, the steam pipe; q, the fly-wheel; r, the spur-wheels; and s, s, the roof.

*Fig. 1202.* is a longitudinal section through the water-wheel, the trough, and the two sluices; in which c is the axle of the water-wheel; d, the paddles; e, the upper sluice, over which the water is thrown; f, the pond or reservoir to receive the water before it is carried off to the nearest river; m, the trough or wheel-race; and g, the sluice to regulate the admission of the water from the land to be drained.

*Fig. 1203.* is a section through the boiler lengthwise; in which a is the boiler; b, the fire-place, and fine round the boiler; i, the ash-pit; k, the safety valve; l, the tube for supplying water to the boiler; m, manhole for cleaning out the boiler; and n, the chimney.
Supplement. Statistics of British Agriculture.

8496. Action of the machine. After these particulars, little description will be needed; for it must be evident that, when the engine is set in motion, it will, by means of the wheel and pinion t, turn the water wheel d'd' about its centre c; and that, when set in motion, each of the arms will lift a quantity of water from the trough, or wheel-race, m, over the sluice e (see fig. 1202.), at a higher level to the pond or reservoir f, whence it may be taken away as circumstances may require.

8497. The expense of the portable steam-engine, exclusive of carriage, and putting up, was about 280L; that of the lifting wheel, exclusive of the masonry, about 70L; and the total expense of the whole about 450L.

8498. The study of chemistry by practical farmers is strongly recommended by most writers on scientific agriculture; but this Dr. Madden considers an error. "I have noticed," he says, "with regret, that almost all the popular works hitherto written upon agricultural science have fallen into the one common error of endeavouring to make a chemist of the practical farmer; the authors all seem to think it necessary that, in order to the improvement of agriculture, every farmer must study chemistry. In this respect, however, I hold a totally different opinion. It appears to me that it would be a precisely analogous case, if writers on climate had said, that, in order to preserve health, it were absolutely necessary that every individual should study medicine. It is not an extended knowledge of chemistry that is required,—it is only a confidence in the results obtained by chemists that is absolutely necessary. If the farmer becomes acquainted with the facts as they apply to his practice, and if he has such confidence in these facts that he is willing to act in accordance to them, there is not the least necessity that he should occupy his time and burden his mind with all the abstruse processes of reasoning and experimental proof by which the chemist has been enabled to trace out their connection with the complex phenomena which they serve to illustrate." (Trans. H. S., vol. xiv. p. 616.)

8499. Improvements. Professor Johnston of Durham, one of our first agri-

Cultural chemists, says, "Farmers are proverbially slow in adopting improvements; it is well that they are so, for if they were to adopt everything which is new, they would most likely suffer many disappointments." The same author observes, that "prudence and economy are the soul of agriculture; and the balance of accounts at the end of the year is the criterion of the system pursued." (G. C., 1843, P. 115.)

8500. Experience and experiments. In Professor Henslow's lectures before the Royal Agricultural Society, the connection between agricultural science and practice is clearly pointed out. Experience is the only source of scientific knowledge, and this can only be obtained by a long series of observations.
and experiments, carried on, not by one person, but by many. Subsequently the Professor drew up a scheme by which the same experiment may be repeated at any number of places all over the country. See his Letters to the farmers of Suffolk (Gard. Mag. 1843, p. 313.), Professor Henslow's scheme for co-operation, and Professor Johnston's suggestions, (G. C. 1843, p. 196.) "All England," Professor Henslow observes, "might be converted into one great experimental farm. If your different agricultural societies would prepare accounts of the exact mode in which some hundred farmers might perform a set of easy comparative experiments at the same time, and send in the results of them. This is what is most needed for accelerating the present jog-trot progress of agriculture into something like a railroad pace of advancing." (G. C. 1843, p. 155.) "True, it does not implicitly to the suggestions of the most celebrated chemists, nor adopt their notions in your practice, without previously making a set of comparative experiments for yourselves, in order to test the value of their suggestions. Secure co-operation; adopt the London, and thousands in attending to the same. The decided improvements in the art of culture will then be stricken out for you, that your important interests will be able to maintain that state of prosperity which is so essential to the general well-being of the country." (G. C. 1843, p. 171.)

5801. Model farms, which for many years have been adopted in France, Germany, and even Russia, have lately begun to be formed in Britain. One is commenced on the estate of Lord Ducie in the vale of Gloucester; one is in progress in Yorkshire, for the Yorkshire Agricultural Society, besides some in Hampshire, Gard. Mag. 1840, p. 1590.

5802. The English Agricultural Society. The idea of this society was first suggested by Lord Spencer, at the dinner after the show of the Smithfield club in the beginning of 1838, and a meeting was held for the purpose in the Cavendish Rooms, Q. J. A., vol. ix. p. 110.

5803. The Royal Agricultural Improvement Society of Ireland was established in February, 1831. An account of its progress will be found in the Brit. Farm. Mag., n. s., vol. vii. p. 74.

5804. Schools for the instruction of farmers' sons in the physical sciences were recommended in 1834 by Mr. William Hawkins, of Hitchin, Hertfordshire, (Q. J. A., vol. ix. p. 39).

5805. A Farmers' lending Library, proposed to be established in Liverpool. (B. F. M., n. s., vol. iv. p. 284.)

5807. The great obstacles to agricultural improvement at present, are want of sufficient capital employed in the cultivation of the land, and the absence of improvement, and the absence of due security to any capital that might be applied; and the uncertainty and illiberal foundation on which agricultural polity rests; and the general aversion of landowners and wealthy individuals to make any outlay that will diminish their yearly revenue; and from their considering capital to consist only in the revenue that is derived from their being capital is so great that it is not easy to be connected with improvements that would increase the yearly profit. A moneyed man buys a portion of land, and expects a certain yearly return from it in an uncultivated state; whereas if any part of the capital were expended in improving the quantity of soil, a greater annual revenue would be derived; for, in many instances, the first crop of improvement has paid rent and all expenses, and left the future return for profit and increase of the annuity. (Donaldson's Treatise on Manures, &c. p. 341.)

CHAP. IV.—Bibliography of British Agriculture, from 1832 to August 1843.
